Certification

I certify that this thesis entitled "Studying the Parameters Affecting the Pressure Drop across the Packed Bed" was prepared by Zainab Talib Abidzaid under my supervision at Nahrain University/College of Engineering in partial fulfillment of the requirements for the degree of Master of Science in Chemical Engineering.

Signature: 
Name: **Dr. Mohammed N. Latif**
(Supervisor)
Date: 5 / 11 / 2007

Signature: 
Name: **Prof. Dr. Qasim J. Slaiman**
(Head of Department)
Date: 11 / 11 / 2007

Certificate

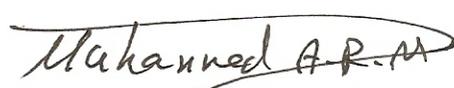

We certify, as an examining committee, that we have read this thesis entitled "Studying the Parameters Affecting the Pressure Drop across the Packed Bed", examined the student **Zainab Talib Abidzaid** in its content and found it meets the standard of thesis for the degree of Master of Science in Chemical Engineering.

Abstract

Semi-empirical equations for fluid flow through packed bed have been achieved, depending on Buckingham π theorem. Two types of fluids have been used (water and air) separately (single phase flow). Several types and kinds of packing materials with different sizes have been used in the packed bed, and each had been studied separately.

Different parameters affecting the pressure drop of fluid flow through packed bed have been studied. These parameters are fluid velocity, bed porosity, bed diameter, sphericity, particle diameter, packing height and wall effect.

A certain semi-empirical equations for fluid flow through packed bed have been achieved for a certain shape and type of packing system called singular equation (mono size spherical particle system, mono size non spherical particle system, binary sized spherical particle system, ternary sized spherical particle system, quaternary sized spherical particle system, quinary sized spherical particle system and multi-sized spherical particle system). There were eleven singular equations have been written, six of them for water flow and five for air flow through packed beds.

A general semi-empirical equation has been achieved that can be used for all shapes and types of packing systems.

The results of calculations from both singular equations and general equation were comparable. The results of all calculations for fluid flow through packed bed have been compared with many documented experimental literatures. This comparison gave a very good agreement, and has been represented in tables and curves. The results from Ergun equation

using similar conditions have been represented in the curves for the sake of comparison.

Porosity empirical formulas had been achieved for all the equations used in the calculations. The calculation results of these formulas have been compared with Furnas equation of porosity and with experimental results taken from documented literature data; the comparisons show a very good agreement between the porosity formulas and experimental results.

The minimum fluidization velocity is an indication for the fluidization point, therefore; a semi-empirical equation based on Leva equation had been modeled to evaluate the minimum fluidization velocity to calculate the fluidization point.

Notations

Symbols	Notations
A	= The bed cross sectional area (m).
a	= Representation of packing and fluid characteristics at laminar flow.
B	= The permeability coefficient for the bed
b	= Representation of packing and fluid characteristics at turbulent flow.
D_R	= Diameter of the bed (m).
d_p	= Diameter of the particle (m).
d_t	= Diameter of tube (m).
d_e	= Equivalent diameter of the pore channels (m).
$d_{p_{eff}}$	= Effective particles diameter (m).
d_{pi}	= Diameter of particle i in mixture (m).
e	= Porosity of the bed.
f_w	= Correction factor.
f	= Friction factor for packed bed.
g	= Acceleration due to gravity, 9.81 (m/s ²).
K	= Dimensionless constant whose value depends on physical properties of the bed and fluid.
K_C	= Kozeny's constant.
L	= The height of packing in the bed (m).
l	= Thickness of the bed (m).
Δp	= Pressure drop through packed bed, Pa (kg/m.s ²).
R	= Reduce of horizontal pipe.

Re_{mf}	=	Reynold number at minimum fluidization velocity.
Re_p	=	Modified Reynolds number for packed bed.
Re	=	Reynolds number.
Δr	=	An annulus thickness of element.
S	=	Specific surface area of the particles (m^2/m^3).
S_p	=	Surface area of a particle (m^2).
S_B	=	Specific surface area of the bed (m^2/m^3).
S_c	=	Surface of the container per unit volume of bed (m^{-1}).
τ_{rz}	=	Shear stress.
u	=	Superficial velocity (m/s).
u_1	=	Average velocity through the pore channels (m/s).
u_{mf}	=	Minimum fluidization velocity (m/s).
u_t	=	Terminal velocity (m/s).
V	=	Volume of the fluid flowing through bed in time t.
V_p	=	Volume of a particle (m^3).
x_i	=	The weight fraction of particle i.

Greek Symbols

ε	=	Porosity of the bed.
ε_{mf}	=	Minimum fluidization porosity of the bed.
μ	=	Fluid viscosity (kg/m.s).
Φ	=	Sphericity.
ρ	=	Density of fluid (kg/m^3).
ρ_p	=	Density of particle (kg/m^3).
ρ_b	=	Bulk density (g/cm^3).
ρ_t	=	True density (g/cm^3).

Chapter One

Introduction

Fluid flow through packed bed has many important applications in chemical and other processes in engineering fields such as fixed-catalytic reactor, adsorption of a solute, gas absorption, combustion, drying, filter bed, distillation, extraction, wastewater treatment and the flow of crude oil in petroleum reservoir [1].

A typical packed bed setup is a cylindrically-shaped column filled with packing materials. The column can vary in diameter, height, and material. The packing material can vary in shape, roughness, and particle size [2,3]. The most important factor in concerning the bed from a mechanical perspective is the pressure drop required for the liquid or the gas to flow through the column at a specified flow rate [4].

The pressure drops in packed beds at different fluid velocities can be modeled using an equation developed by Sabri Ergun [5]. The pressure drops in this model applies to a broad spectrum of fluids and packing materials, but it does not predict pressure drop behavior after the point of fluidization because of bed expansion and changes in packing void fraction [6]. Ergun's equation does not take in consideration wall effects, which represents pipe like flow around the edges of the column [7,8]. Ergun believed that the pressure drop over the length of the packing was dependent upon rate of fluid flow, viscosity and density of the fluid, closeness and orientation of packing, size, shape, and surface of the packing material [9].

The advantage of using packed column rather than just tank or other reaction vessel is that the packing affords a large contacting surface area for fluids [10]. Usually increased surface area provides a high degree of turbulence in the fluids which are achieved at the expense of increased capital cost and/or pressure drop, and a balance must be made between these factors when arriving at an economic design [7].

The aim of this work is to:

- I. Writing a semi-empirical equation for fluid flow through packed beds, and studying the effect of different parameters on pressure drop of fluid flow through packed beds, like fluid velocity, height of packing, type of packing materials, particles size, bed porosity and bed diameter. The semi-empirical equations includes:
 - a. A general semi-empirical equation that can be used for all types of packing systems for water and air flow through packed beds.
 - b. A partial semi-empirical equation (singular) for each type of packing systems.
- II. Writing porosity formulas fitted to the semi-empirical equations.
- III. Writing a semi-empirical equation to evaluate the minimum fluidization velocity, in order to determine the working range of the written equations, this is in the fixed region of the fluid flow diagram.

Chapter Two

Literature Survey and Theoretical Background

2.1 Introduction

A packed bed is simply a vertical column that is partially filled with small media varying in shape, size, and density. A fluid (usually air or water) is passed through this column from the bottom and the pressure is measured by two sensors above and below the packed bed. This packed bed becomes “fluidized” when the fluid flows at such a high velocity that the closely packed particles are freed and the space between the packing increases and the particles appear to float and oscillate slightly in the column so the mixture behaves as though it is a fluid [11]. The pressure drop in packed and fluidized beds depends on the type of packing, the bed void fraction, properties of the fluid, column diameter, and also the flow rate of fluid [12].

2.2 Packed Beds

The flow of fluid through bed composed of stationary granular particles is a frequent occurrence in the chemical industry and therefore expressions are needed to predict pressure drop across beds due to the resistance caused by the presence of the particles [13].

Packed systems in industry may be divided into the following classes:

1. Fixed beds
 - a. Solid- gas system.
 - b. Solid- liquid systems.
2. Moving beds.
3. Solid- liquid- gas system.

Typical example of solid-gas fixed-bed systems are the catalytic reactors which were used by the Germans in the Fischer-Tropsch synthesis retorting of oil Shale, roasting of ores, combustion of coal and coke in fuel beds, and blast furnace operations [14].

The most important solid-liquid fixed-bed applications are water filtration, flow of oil through sand strata, coal washing, and leaching [15].

Moving beds are employed in the FCC (fluidized catalytic cracking) process and CFBC (Circulating Fluidized Bed Combustion) [16].

The solid-liquid-gas system comprises fractionating towers, absorbers, scrubbers, and many other kinds of chemical engineering equipment [14]

2.3 Fluidized Beds

A fluidized bed is a packed bed through which fluid flows at such a high velocity that the bed is loosened and the particle-fluid mixture behaves as though it is a fluid [17].

Fluidization has been an important part of chemical industry since the early 1900s through processes such as petroleum cracking beds, polymer production, aquatics, and the food industry. Fluidization is a process where solid particles are transformed into a fluid like state through suspension in liquid or

gas media. First references to fluidization behavior date all the way back to 1556, but the use of fluidization in a more practical sense did not occur until the nineteenth century [18].

2.4 Specific Surface Area

The specific surface area of a particle is used through most of the equations or formulas of fluid flow through packed bed, and it is defined as follows:

$$S = \frac{S_p}{V_p} \quad \dots (2.1)$$

Where S is specific surface area of a particle in m^{-1} , S_p is the surface area of a particle in m^2 and V_p is the volume of a particle in m^3 . Therefore for spherical particle:

$$S = \frac{\pi d_p^2}{\pi (d_p^3 / 6)} = \frac{6}{d_p} \quad \dots (2.2)$$

Where d_p is the particle diameter in m [19,7].

2.5 Void Fraction

The void fraction is the voided volume between packing particles in a column. It can be defined as the ratio of the empty volume to the total volume of the bed [20], i.e:

$$\varepsilon = \frac{\text{Volume of voids in a bed}}{\text{total volume of the bed}} \quad \dots (2.3)$$

Other names given to the void fraction are porosity, fractional voidage, or simply voidage. The liquid in a packed bed usually fills this voided volume. For spherical packing, geometric analysis predicts that the void fraction will be

constant with consistent packing methods, regardless of the diameter of the spheres [21].

The porosity has a great effect on the properties of packed beds. There is no doubt that any small change in porosity of the bed leads to a big change in pressure drop across the bed. **Leva in 1951** [22] found that a 1% decrease in the porosity of the bed produced about an 8% increase in the pressure drop, whilst **Carman in 1956** [23] reported a higher value, 10% increase in the pressure drop for every 1% decrease in porosity [24].

2.6 Shape Factor

For fluid flow through packed beds many particles of irregular shapes usually used. To treat this problem the particles are considered as spheres by introducing a factor called sphericity Φ which allows calculation of an equivalent diameter [25].

The sphericity of a particle is the ratio of the surface area of this sphere having the same volume as the particle to the actual surface area of the particle, as shown below:

$$\Phi = \frac{a_{sphere}}{a_{particale}} = \frac{6/d_p}{S_{particle}/V_{particle}} \quad \dots (2.4)$$

For a sphere, the surface area $S_p = \pi d_p^2$ and the volume is $V_p = \pi d_p^3/6$. Table 2.1 below shows the shape factor for different packing geometries [21].

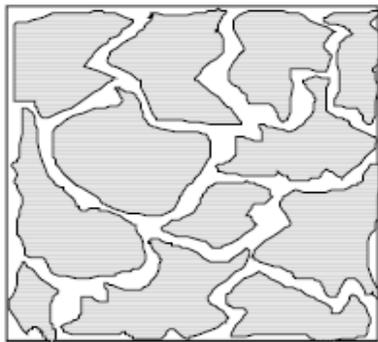

Table 2.1 Shape factor for different particles [26, 27]

<i>Material</i>	<i>Shape Factor</i>	<i>Material</i>	<i>Shape Factor</i>
Spheres	1.0	Flint sand	0.65
Cubes	0.81	Crushed glass	0.65

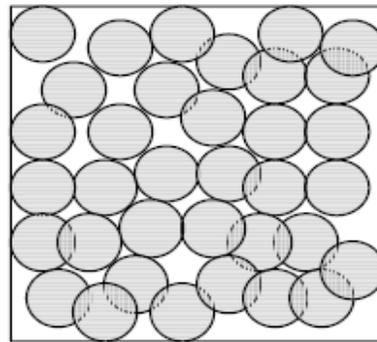

Cylinders, $d_p=L$ (length)	0.87	Coal dust	0.73
Berl saddles	0.3	Mica flakes	0.28
Rasching rings	0.3	Rounded sand	0.83
Sands, average	0.75	Ottawa sand	0.95

The shape factor is difficult to evaluate when dealing with small irregular shapes. The particle shape affects the packed bed resistance in two ways [24]:

- i) The fluid paths in beds of irregular particles are more tortuous than those in similar beds of spheres (Fig.2.1).
- ii) It have voids differing in both size and shape from those of similar beds consisting spheres.

a. irregular particles

b. regular particles

Figure 2.1 Different shapes of particles [28]

2.7 Parameters Affecting Fluid Flow Through Packed Beds

The variables affecting resistance to flow through a packed bed can be classified into two basic categories [24]:

1. Parameters related to the fluid flowing through the bed such as viscosity, density, and rate of fluid flow.
2. Parameters related to the nature of the bed are numerous and to be considered as shape and size of the particles, container walls effects, porosity of the bed, surface roughness of the particle, and orientation of particles.

2.8 Container Walls Effects

The walls retaining a packed bed affect the resistance of the fluid flow in two ways [24]:

- i) The particles adjacent to the walls pack more loosely than those more remote from them thus increasing the porosity of the zone near the walls. Figure 2.2 shows the fluctuation of porosity in a bed of spheres and cylinders.
- ii) They create an additional surface area providing additional resistance to flow.

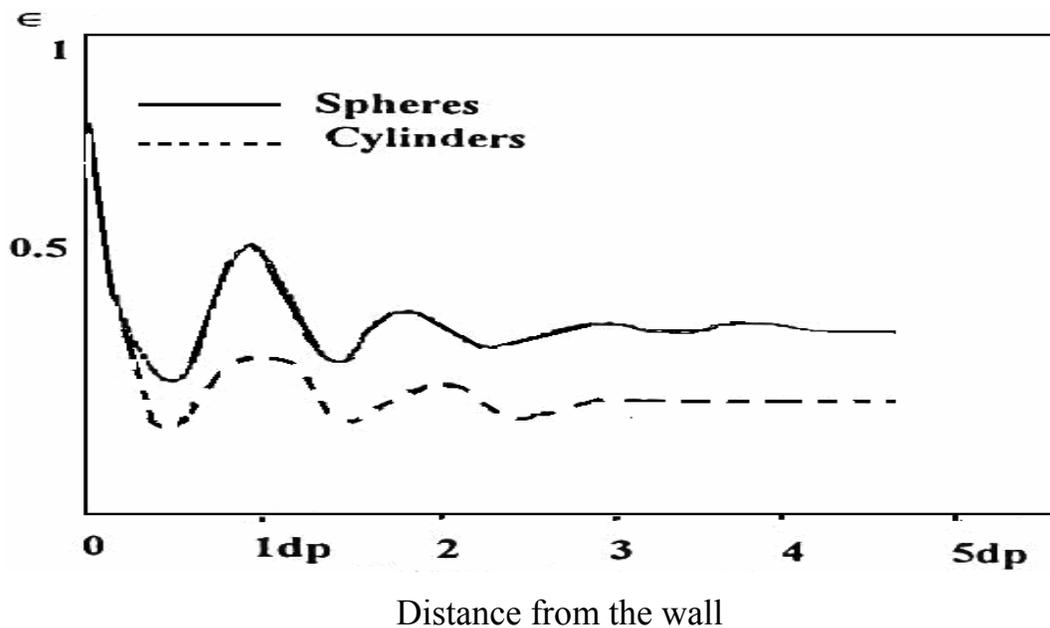

Figure 2.2 The Fluctuation of porosity in a bed of spheres and cylinders [29]

To decrease wall effects, the particle diameter should be small in comparison with the column diameter in which the packing is contained [30]. **Furnas** in 1931 [31] studied the wall effect and found that when the ratio of the column diameter to the particle diameter is greater than 10:1, the wall effect can be neglected. **Carman** in 1937[33] and **Coulson** in 1949[34] made no correction for the change in porosity near to the wall. They used the mean porosity and for low rates added half the area

of the walls to the surface area of the particles. **Graton and Fraser** in 1953 [32] showed that the porosity of the bed is greater in the layers next to the wall, which lead to increase the fluid permeability there. A wall effect correction factor f_w for velocity through packed bed has been determined experimentally by **Coulson** [7] as:

$$f_w = \left(1 + \frac{1}{2} \frac{S_c}{S}\right)^2 \quad \dots (2.5)$$

Where: S_c is the surface of the container per unit volume of bed.

S is the specific surface area of the particles.

Numerous investigators including **Carman** in 1937, **Sullivan and Hertel** in 1940, **Coulson** in 1949, and **Leva** in 1959 have stated that at high flow rates the wall effect is negligible. On the contrary, **Dudgeon** in 1964 believed that the wall effect was independent of the flow rate, but his work has been subjected to considerable criticism by **Franzini** in 1967 [24].

2.9 Theoretical Basis of Fluid Flow through Packed Beds and Previous Work

The first experimental work on the subject was carried out by **Darcy** in 1830 [35] in Dijon when he examined the rate of flow of water from the local fountains through beds of sand of various thicknesses. He states an empirical linear relationship between the flow rate and pressure gradient such that “the volume rate of flow is directly proportional to the pressure drop and inversely proportional to the thickness of the bed.” This relation, often termed Darcy’s law, has subsequently been confirmed by a number of workers and can be written as follows:

$$u = K \frac{(-\Delta P)}{l} \quad \dots (2.6)$$

where $-\Delta P$ is the pressure drop across the bed, l is the thickness of the bed, u is the average velocity of flow of the fluid, defined as $(1/A)(dV /dt)$, A is the total cross sectional area of the bed, V is the volume of fluid flowing in time t , and K is a constant depending on the physical properties of the bed and fluid.

The linear relation between the rate of flow and the pressure drop leads one to suppose that the flow was streamline, this would be expected because the Reynolds number for the flow through the pore spaces in a granular material is low, since both the velocity of the fluid and the width of the channels are normally small. The resistance to flow then arises mainly from viscous drag. Equation 2.6 can then be expressed as:

$$u = B \frac{(-\Delta P)}{\mu l} \quad \dots (2.7)$$

where μ is the viscosity of the fluid and B is termed the permeability coefficient for the bed, and depends only on the properties of the bed. The value of the permeability coefficient is frequently used to give an indication of the ease with which a fluid will flow through a bed of particles or a filter medium. The values of B apply only to the laminar flow region for various types of packing [36].

Hagen in 1839 [37], carried out the first carefully documented friction experiments in low-speed tube laminar flow, from which the **Hagen-Poiseuille law** [38] arose, this law experimentally derived in 1838 from the Darcy's law, formulated and published in 1840 and 1846. Poiseuille's law or the Hagen-Poiseuille law is a physical law concerning the voluminal laminar stationary flow of Newtonian fluid through a cylindrical tube with constant circular cross-section [39].

Considering a horizontal pipe of radius R and length L with an annulus element of thickness Δr as shown in figure 2.3 below [41]:

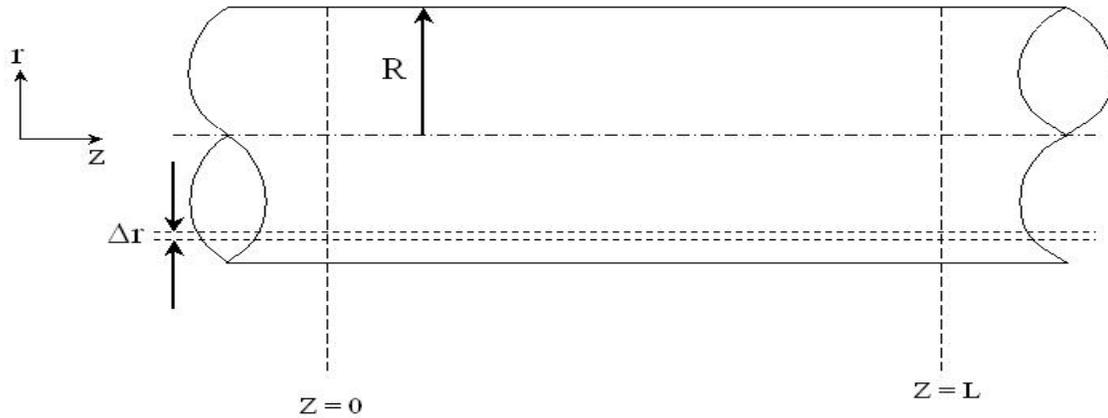

Figure 2.3 Schematic diagrams for a pipe

The momentum balance on the increment is as follows:

$$\text{rate of momentum in} - \text{rate of momentum out} + \text{sum of forces acting on system} = \text{accumulation} \quad \dots (2.8)$$

1. Rate of momentum in across cylindrical surface = $(2\pi r L) \tau_{rz}|_r$
2. Rate of momentum out across cylindrical surface = $(2\pi r L) \tau_{rz}|_{r+\Delta r}$
3. Rate of momentum in across annular surface at $z = 0$ is
 $(2\pi r \Delta r u_z)(\rho u_z)|_{z=0}$
4. Rate of momentum out across annular surface at $z = L$ is
 $(2\pi r \Delta r u_z)(\rho u_z)|_{z=L}$
5. Pressure force acting on system = $(2\pi r \Delta r)(P_0 - P_L)$

Where P_0 and P_L is the fluid pressure at $z=0$ and at $z=L$, respectively.

For horizontal pipe the gravitational force is neglected.

Substitution of the above five terms into the general momentum balance equation (2.8):

$$(2\pi r L) (\tau_{rz}|_r - \tau_{rz}|_{r+\Delta r}) + (2\pi r \Delta r u_z) (\rho u_z)|_{z=0} - (2\pi r \Delta r u_z) (\rho u_z)|_{z=L} + (2\pi r \Delta r) (P_0 - P_L) = 0 \quad \dots (2.9)$$

Since the velocity is constant along the z – axis the net of the momentum across the annulus is zero arranging and dividing equation (2.9) by $(2\pi L \Delta r)$ give the following[40]:

$$\frac{d}{dr}(r\tau_{rz}) = \frac{(P_0 - P_L)}{L}r \quad \dots (2.10)$$

integrating equation (2.10) as follows:

$$\tau_{rz} = \frac{(P_0 - P_L)}{2L}r + \frac{C_1}{r} \quad \dots (2.11)$$

using the boundary condition at $r = 0$, $\tau_{rz} = 0$ which leads to make the shear stress to reach infinity therefore C_1 must be zero

$$\tau_{rz} = \frac{(P_0 - P_L)}{2L}r \quad \dots (2.12)$$

the shear stress is defined as follows:

$$\tau_{rz} = -\mu \frac{du_z}{dr} \quad \dots (2.13)$$

substituting equation (2.13) into (2.12) and arranging

$$\frac{du_z}{dr} = \frac{(P_0 - P_L)}{2\mu L}r \quad \dots (2.14)$$

Integrating equation (2.14)

$$u_z = \frac{(P_0 - P_L)}{4\mu L}r^2 + C_2 \quad \dots (2.15)$$

B. C. at $r = R$, $u_z = 0$

$$C_2 = -\frac{(P_0 - P_L)}{4\mu L}R^2 \quad \dots (2.16)$$

Substituting equation (2.16) into (2.15) and arranging

$$u_z = \frac{(P_0 - P_L)}{4\mu L}R^2 \left(1 - \left(\frac{r}{R} \right)^2 \right) \quad \dots (2.17)$$

Equation (2.17) is the velocity distribution inside pipe as a function of the radius.

The average velocity is obtained by the following expression [41] as follows:

$$u = \frac{\int_0^{2\pi} \int_0^R r u_z dr d\theta}{\int_0^{2\pi} \int_0^R r dr d\theta} \quad \dots (2.18)$$

Substitution of equation (2.17) into (2.18) and integrating gives

$$u = \frac{\Delta P d_t^2}{32 \mu L} \quad \dots (2.19)$$

Rearranging equation (2.19) gives

$$\frac{\Delta P}{L} = \frac{32 \mu u}{d_t^2} \quad \dots (2.20)$$

Where equation (2.20) is the Hagen-Poiseuille equation [39].

Considering a unit volume packed bed, the volumes occupied by the voids and the solid particles are ε and $(1-\varepsilon)$ respectively, where ε is the void fraction or porosity of the bed. Let S is the surface area per unit volume of the solid material in the bed. Thus the total surface area (S_B) in a packed bed of unit volume is $(1 - \varepsilon) S$.

An equivalent diameter d_e for flow through the bed can be defined as four times the cross-sectional flow area divided by the appropriate flow perimeter. For random packing, this is equal to four times the volume occupied by the fluid divided by the surface area of particles in contact with the fluid. Thus, the equivalent diameter is:

$$d_e = \frac{4\varepsilon}{(1-\varepsilon)S} \quad \dots (2.21)$$

If the free space in the bed is assumed to consist of a series of tortuous channels, then equation (2.19) for flow through a bed may be rewritten by the substitution of the equivalent diameter:

$$u_1 = \frac{\Delta P}{32 \mu L} \left(\frac{16 \varepsilon^2}{(1-\varepsilon)^2 S^2} \right) \quad \dots (2.22)$$

The average velocity through the pore channels (u_1) is defined as the superficial velocity (u) divided by the porosity of the bed [42]. Therefore equation (2.22) will be as follows:

$$u = \frac{\Delta P}{2\mu L} \left(\frac{\varepsilon^3}{(1-\varepsilon)^2 S^2} \right) \quad \dots (2.23)$$

Replacing equation (2.23) by the following equation:

$$u = \frac{\Delta P}{K_c \mu L} \left(\frac{\varepsilon^3}{(1-\varepsilon)^2 S^2} \right) \quad \dots (2.24)$$

Where K_c values [37,7] are given in the following figure:

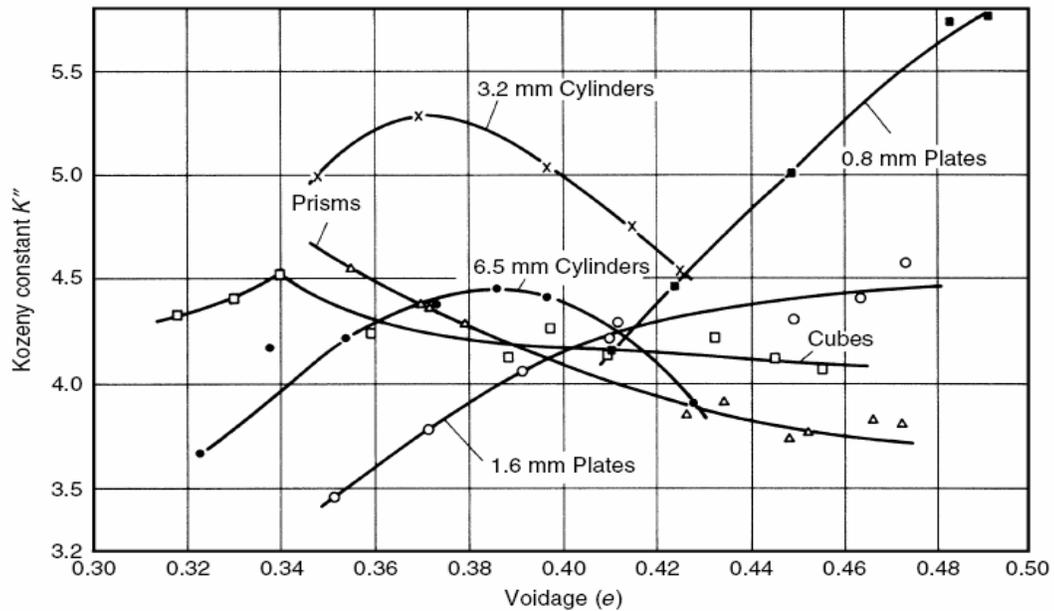

Figure 2.4 Variation of **Kozeny's** constant K_c with porosity for various shapes [7]

Forchheimer in 1901 [43] proposed a quadratic equation for the non-linear flow region:

$$\frac{\Delta P}{L} = au + bu^2 \quad \dots (2.25)$$

where u is the fluid velocity, ΔP is the pressure drop, L is the length of the medium,

and a, b are factors which depend on both fluid and porous medium properties. The expression for a and b has been studied by many investigators (e.g., **Forchheimer** in 1930 [44], **White** in 1935[45], **Carman** in 1937[33], **Ergun** in 1952 [46], **Schneebeli** in 1955 [47], **Irmay** in 1964 [48]; **Ward** in 1964 [49]; **Blick** in 1966 [50]; **Ahmad** in 1967[51]; **Scheidegger** in 1974 [52]). The most widely used expression for a and b is that given by **Ergun** in 1952 [46].

Forchheimer [43] includes the kinetic effect of fluid which is not included in the models for small-Reynolds-number flows. For this reason, he suggested that a term representing the kinetic energy of fluid should be included, i.e. the resulting equation is of the form:

$$\frac{\Delta P}{L} = \frac{\mu}{B} u + a \rho u^2 \quad \dots (2.26)$$

The origin of the terms in equation (2.26) indicates that the linear term represents a flow resistance due to viscous shear. The quadratic term represents the kinetic energy losses.

Carman and Kozeny [53] derived an expression for pressure drop under viscous flow as:

$$\frac{\Delta p}{L} = \frac{150 (1-\varepsilon)^2 u \mu}{\varepsilon^3 \emptyset^2 d_p^2} \quad \dots (2.27)$$

Burke and Plummer [54] derived an expression for change in pressure at turbulent flow resulting from kinetic energy losses as:

$$\frac{\Delta p}{L} = \frac{1.75(1-\varepsilon)\rho u^2}{\varepsilon^3 \emptyset d_p} \quad \dots (2.28)$$

Ergun in 1952 [46] proposed a semi-empirical equation by adding the Carman-Kozeny equation for purely laminar (viscous) flow through a porous

medium modeled as an assembly of capillaries, to the Burke-Plummer equation derived for the fully turbulent limit in a capillarie medium.

$$\frac{\Delta P}{L} = 150 \frac{\mu u (1-\varepsilon)^2}{\phi^2 d_p^2 \varepsilon^3} + 1.75 \frac{\rho u^2 (1-\varepsilon)}{\phi d_p \varepsilon^3} \quad \dots (2.29)$$

Where ΔP , ε , ρ , d_p , Φ , u , L , and μ are the pressure drop, void fraction of the bed, density of the fluid, particle diameter, sphericity of the particle, fluid velocity, height of the bed, and the fluid viscosity respectively. Ergun equation is a unique among many equations because it covers any flow type and condition (laminar, transitional and turbulent) [6].

For beds consisting of a mixture of different particle diameters, the effective particle diameter ($d_{p,eff}$) can be used instead of d_p (in equation 2.29) as:

$$d_{p,eff} = \frac{1}{\sum_{i=1}^n \frac{x_i}{d_{pi}}} \quad \dots (2.30)$$

Where x_i is the weight fraction for particle of size d_{pi} [55,21].

Davidson and Turk in 1954 [56] studied the flow of hydrogen, nitrogen and argon through packed beds of lamp-and carbon-blacks at atmospheric pressure and very low gas velocities. These materials can be packed to cover an appreciable range of porosities and so permit examination of the relationship between porosity and permeability over a wide range. They found that the porosity functions suggested by Kozeny, Carman and Arnell are not applicable to such beds; the permeability of the bed is related to the fourth power of the bed density.

The Ergun equation was developed for incompressible packed beds composed of uniform spherical particles. Despite this, the Ergun model has been used in situations where the particle shape was non-spherical and/or the particle size

distribution was non-uniform (**MacDonald et al.**, 1979[57]), as well as for wood chips. For non-uniform particle size distributions, the volume-surface mean diameter has been found to best describe flow through the packed bed (**Comiti and Renaud**, 1989[58]).

Ergun used fitted parameters for spheres (A and B) as (150 and 1.75) as represented in equation 2.29 above. In recent years many investigators used Ergun equation to model fluid pressure drop through packed beds of different particles shapes , As shown in table 2.2 below, the values of A and B are significantly greater than those found by Ergun and others for a wide range of particles at bed void fractions above 0.35. However, **Francher and Lewis (Macdonald et al.**, 1979[57]) also reported much higher values of A and B for beds of consolidated granular material (e.g. sandstone particles) with low void fractions ($\epsilon < 0.3$) (i.e. A = 750 to 5500. **Francher and Lewis** report negative values of B in some cases, as has been found for wood chips (**Lee and Bennington**, 2004[59]). Although there is a monotonic increase in both A and B as the average chip diameter increases there is clearly more to the dependence than this. For example, for the pin chips A is independent of chip diameter while B increases with it. **Quak and Chad** in 2005 [61] used Ergun equation to model fluid pressure drop through packed beds of wood chips (parallelepiped particles) having a range of size distributions. The bed void fraction and the liquid velocity were changed to cover the range of conditions expected in commercial digesters. As in past work with wood chips the average bed voidage was used in the correlations. **Quak and Chad** tests showed that when compacted, the void fraction in the chip column was not uniform, likely due to normal forces generated within the column and the resulting increase in friction between the chips and the vessel wall [61].

Table 2.2 Measured parameters of Ergun equation for different research's using different particles shapes [61].

Particle		Void fraction (-)	Superficial velocity (mm/s)	Ergun parameters		Reference

Syamlal in 1987 [62] derived a formula for the multi-particle drag coefficient from a Richardson-Zaki type velocity-voidage correlation and a formula for the single-particle drag coefficient. The formula was based on two parameters only, the Reynolds number and the void fraction. The formula was compared with the Ergun equation for a void fraction range of 0.5-0.6 and correctly reduced to a formula for the single-particle drag coefficient, for void fraction of 1.0. The minimum fluidization velocity calculated from the formula compared well with experimental data for Reynolds numbers greater than 10.

Stichlmair, Bravo and Fair in 1989[63] developed a generalized model for the prediction of pressure drop and flooding in packed columns in which gas and liquid flow counter currently. The model has been validated for a wide variety of packing, both random and structured. A single mathematical expression is used to describe all flow regimes: dry gas, irrigated gas flow below the load point, loading region, and flooding.

Shenoy et. al in 1996[64] developed a theoretical model for the prediction of velocity and pressure drop for the flow of a viscous power law fluid through a bed packed with uniform spherical particles. The model was developed by volume averaging the equation of motion. A porous microstructure model based on a cell model is used. Numerical solution of the resulting equation is effected using a penalty Galerkin finite element method. Experimental pressure drop values for dilute solutions of carboxymethylcellulose flowing in narrow tubes packed with uniformly sized spherical particles are compared to theoretical predictions over a range of operating conditions. The extra pressure drop due to the presence of the wall is incorporated directly into the model through the application of the no-slip boundary condition at the container wall. The extra pressure drop reaches a maximum of about 10% of the bed pressure drop without wall effect. The wall effect increases as the ratio of tube diameter to particle diameter decreases, as the Reynolds number decreases and as the power law index increases.

Grulovic and Zdanski in 1999[65] proposed a method for the determination of the terminal velocity of non-spherical particles and compared with experimental data. The method is based on particulate expansion data of fluidized bed and variational model for calculating fluid-particle interphase drag coefficient.

Lee in 2002[66] measured the pressure drop through column of industrial white spruced chips (produced with a chipping head ring) as a function of chip size distribution and the extent of delignification, he also studied how flow resistance

which is depended on porosity is affected by the kappa number of chips, which affect their flexibility, and chip size distribution, the compaction forces applied to the column, and the liquid superficial velocity. The chips bed was compressible and inelastic.

Basu et. al. in 2003[11] studied the effect of various velocity range on the packed bed column and took their observations of the packing height and pressure drop in the column their observations were recorded for each trial consisting of a certain initial bed height , column width, and packing material. The two columns used had diameters of 3.5 and 6 inches; the packing materials used were half-inch plastic marbles and pea gravel. They found that the pea gravel followed Ergun equation best.

Ibrahim and Hashim in 2004[67] studied the pressure drop during single fluid phase flow to determine the pressure drop characteristic of the porous media (glass ballotini particulate beds) for coalescence. It is also served to check the reproducibility of the packing technique, and to detect any foreign particulate matter or re-arrangement of the individual particles in the coalesce bed. Furthermore their data provided a basis for comparison with that during two-phase flow with coalescence.

Vivas et. al in 2005[68] studied the macroscopic flow through a two dimensional porous medium model by numerical and experimental methods. The objective of their research is to develop an empirical model by which the pressure drop can be obtained. In order to construct the model, they used a series of blocks as an idealized pressure drop device, so that the pressure drop can be calculated. The range of porosities studied is between 28 and 75 per cent. They found that the pressure drop is a combination of viscosity and inertial effects, the later being more important as the Reynolds number is increased. The empirical equation obtained in this investigation was compared with the Ergun equation.

Hellström and Lundström in 2006[69] suggested a model for flow through porous media taking into consideration the inertia-effects. They used the empirically derived Ergun equation that can describe the response of several porous media but does not reveal the real mechanisms for the flow. In order to increase the understanding of such flows they performed a micro-mechanically based study of moderate Reynolds number flow between parallel cylinders using a Computational Fluid Dynamics approach. Main results are that the Ergun equation fits well to simulated data up to Reynolds number of 20, that inertia-effects must be taken into account when Reynolds number exceeds 10 and that results from stationary simulations replicate time resolved ones at least up to Reynolds of 880.

Chung and Long in 2007[70] studied how the pressure drop of a packed bed is related to the flow rate of the fluid coming into the column , they used particles such as pea gravel, marbles and glass marbles. From the data collected the pressure drop was determined which was then compared to the pressure drop predicted by the Ergun equation. They found that Ergun equation better modeled the marbles due to their more fixed void fraction.

2.10 Minimum Fluidization Velocity

The basic of the theory for prediction of the minimum fluidization velocity is that the pressure drop across the bed must be equal to the effective weight per unit area of the particles at the point of incipient fluidization, this expressed mathematically as follows [17]:

$$\frac{\Delta P}{L} = (\rho_p - \rho) (1 - \varepsilon_{mf}) g \quad \dots (2.31)$$

equation (2.29) can now be used for small extrapolation for packed beds to calculate the minimum fluidization velocity at which fluidization begins as follows [71]:

$$\frac{1.75 d_p^2 u_{mf}^2 \rho^2}{\phi \varepsilon_{mf}^3 \mu^2} + \frac{150 (1 - \varepsilon_{mf}) d_p u_{mf} \rho}{\phi^2 \varepsilon_{mf}^3 \mu} - \frac{d_p^3 \rho (\rho_p - \rho) g}{\mu^2} = 0 \quad \dots (2.32)$$

defining a Reynolds number as:

$$Re_{mf} = \frac{d_p u_{mf} \rho}{\mu} \quad \dots (2.33)$$

so that equation (2.32) will be as follows:

$$\frac{1.75 Re_{mf}^2}{\phi \varepsilon_{mf}^3} + \frac{150 (1 - \varepsilon_{mf}) Re_{mf}}{\phi^2 \varepsilon_{mf}^3} - \frac{d_p^3 \rho (\rho_p - \rho) g}{\mu^2} = 0 \quad \dots (2.34)$$

when $Re_{mf} < 10$ (small particles), the first term can be dropped as follows:

$$u_{mf} = \frac{(\rho_p - \rho) g d_p^2 \varepsilon^3}{150 \mu (1 - \varepsilon)} \quad \dots (2.35)$$

and when $Re_{mf} > 1000$ (large particles), the second term dropped out[60].

Leva in 1959 [22] made a semi-empirical equation for the prediction of minimum fluidization velocity for gas fluidization as shown below:

$$u_{mf} = \frac{0.0093 d_p^{1.82} (\rho_p - \rho)^{0.94}}{\mu^{0.88} \rho^{0.06}} \quad \dots (2.36)$$

Wen and Yu in 1966 [72] produced an empirical correlation for u_{mf} for gas fluidization the Wen and Yu correlation is often taken as being most suitable for particles larger than 100 μm , whereas the correlation of **Baeyens** in 1974 [73], shown below in equation (2.37), is best for particles less than 100 μm .

$$u_{mf} = \frac{d_p^{1.8} (\rho_p - \rho)^{0.934} g^{0.934}}{110 \mu^{0.87} \rho^{0.066}} \quad \dots (2.37)$$

Figure 2.5 below shows that particles remains packed in the bed as long as the gravitational force is greater than the force exerted by the upward fluid flow from the bottom of the column. However, when the force exerted by the upward fluid flow equals the gravitational force, the bed will start to expand [74].

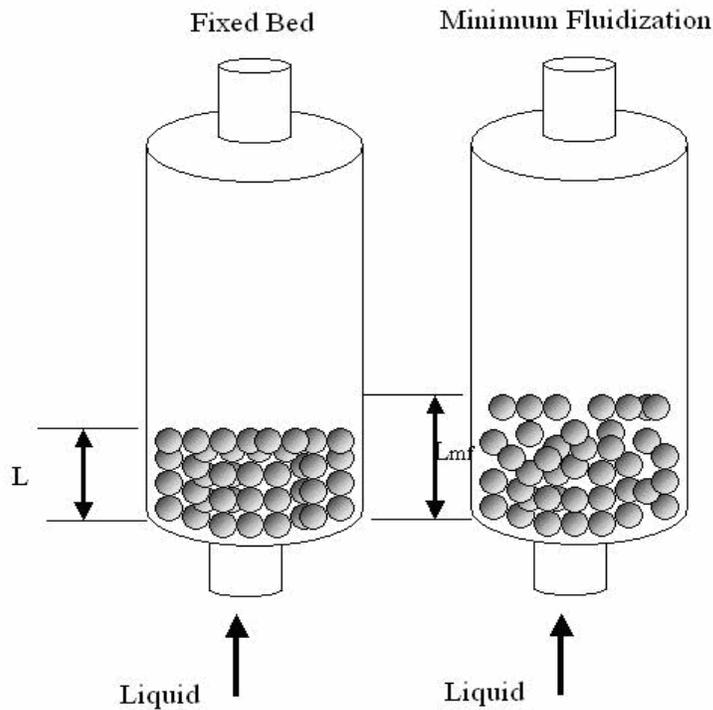

Figure 2.5 Pictorial Representation of the Fluidization Process [18]

Figure 2.6 below illustrate the regions of pressure drop when velocity increased to and beyond minimum fluidization velocity [75].

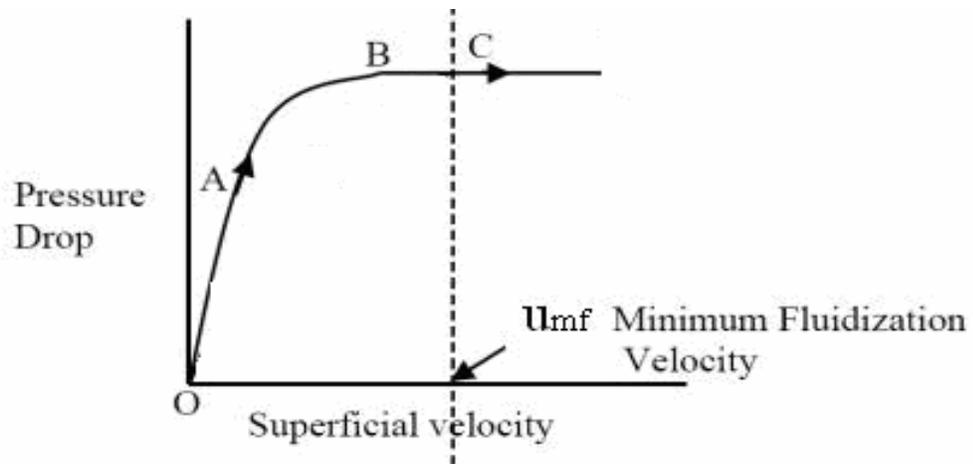

Figure 2.6 Pressure drop versus superficial velocity

At first, when there is no flow, the pressure drop zero, and the bed has a certain height. As the superficial velocity increased tracing the path ABC, at first, the

pressure drop gradually increases while the bed height remains fixed. This is a region where the Ergun equation for a packed bed can be used to relate the pressure drop to the velocity which is the laminar fluid flow region. When the point B is reached, the bed starts expanding in height while the pressure drop levels off and no longer increases as the superficial velocity is increased. This is when the upward force exerted by the fluid on the particles is sufficient to balance the net weight of the bed and the particles begin to separate from each other and float in the fluid. As the velocity is increased further, the bed continues to expand in height, but the pressure drop stays constant [73]. It is possible to reach large superficial velocities without having the particles carried out with the fluid at the exit. This is because the settling velocities of the particles are typically much larger than the largest superficial velocities used. The point C is defined as the **minimum fluidization velocity (u_{mf})** [71].

When the fluid velocity is increased beyond u_{mf} , three types of particle behavior are possible: slugging fluidization, turbulent fluidization, and entrained flow. These three regions are shown in figure 2.7 below:

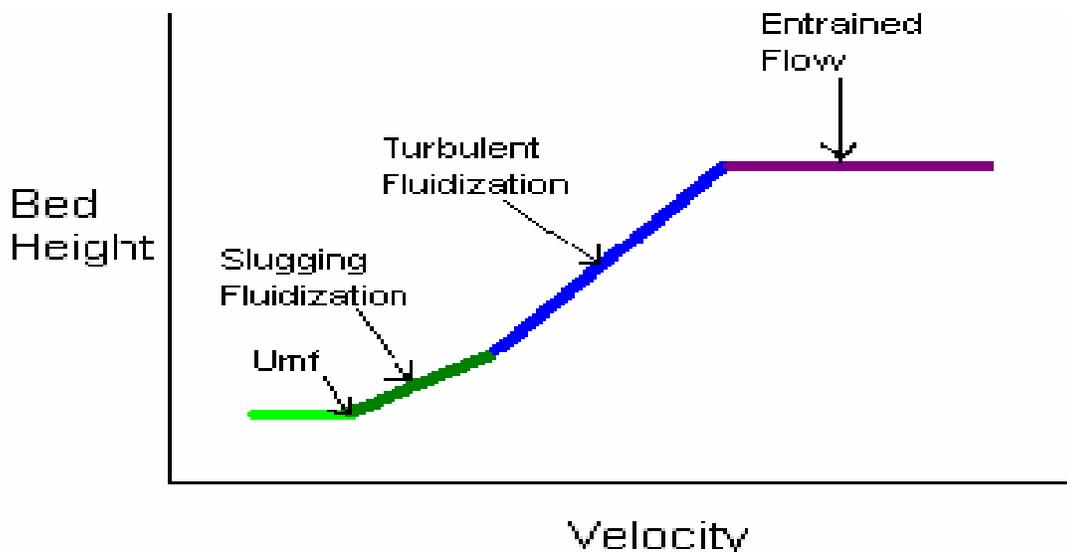

Figure 2.7 Division of three different phases of fluidization [75]

During the onset of slugging fluidization, the pressure drop initially increases with increases in fluid velocity. Slugging behavior is characterized by a continually oscillating bed height at constant fluid velocities [79]. In addition, the bottom layer of the packed particle undergoes turbulent fluidization. As the water velocity continues to increase even more, the pressure drop begins to decrease as the system makes the transition from slugging behavior to turbulent behavior. Turbulent behavior is characterized by a constant bed height at constant fluid velocities with continuous agitation and mixing. While undergoing turbulent behavior, the pressure drop remains constant with increasing fluid velocities [76].

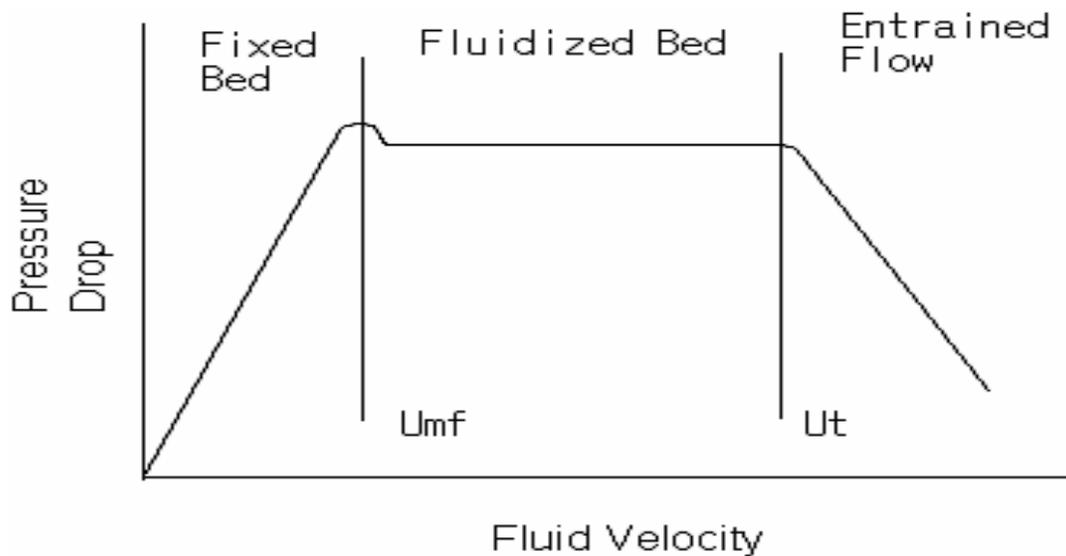

Figure 2.8 The pressure drop across a fluidized bed as a function of fluid velocity

Figure 2.8 [60] above shows that the pressure drop increases with increasing velocity up until u_{mf} as the fluidization enters the entrained flow phase, when the fluid velocity is increased beyond u_t (terminal velocity), the pressure drop decreases as there is decreased resistance to fluid flow [74].

2.11 Friction factor

The most important issue for mechanical perspective for liquid or gas flow through packed bed depends on the pressure drop and friction [75].

Ergun in 1952[46,77] derived a correlation for the friction factor in a column as a function of the Reynolds number, by adding the Blake-Kozeny equation for purely laminar (viscous) flow through a porous medium modeled as an assembly of capillaries, to the Burke-Plummer equation derived for the fully turbulent limit in a capillarie medium as follows:

$$f = \frac{150}{\text{Re}_p} + 1.75 \quad \dots (2.38)$$

Where f is the friction factor which is a dimensionless value that accounts for the degree energy loss due to viscosity and kinetics, defined as (Bird et. al., 1996) [41]:

$$f = \frac{\Delta P}{L} \frac{d_p}{\rho u^2} \left(\frac{\varepsilon^3}{1 - \varepsilon} \right) \quad \dots (2.39)$$

While Re_p is the modified Reynolds number for packed bed defined as (Bird et.al., 1996 [41]):

$$\text{Re}_p = \frac{\rho u d_p}{\mu(1 - \varepsilon)} \quad \dots (2.40)$$

where: Δp is the pressure drop across the bed, L is the length of the bed, d_p is the equivalent spherical diameter of the packing, ρ is the density of fluid, μ is the dynamic viscosity of the fluid, u is the superficial velocity, and ε is the void fraction of the bed.

Equation 2.38 is plotted in figure 2.9 below, f vs. Re_p [96].

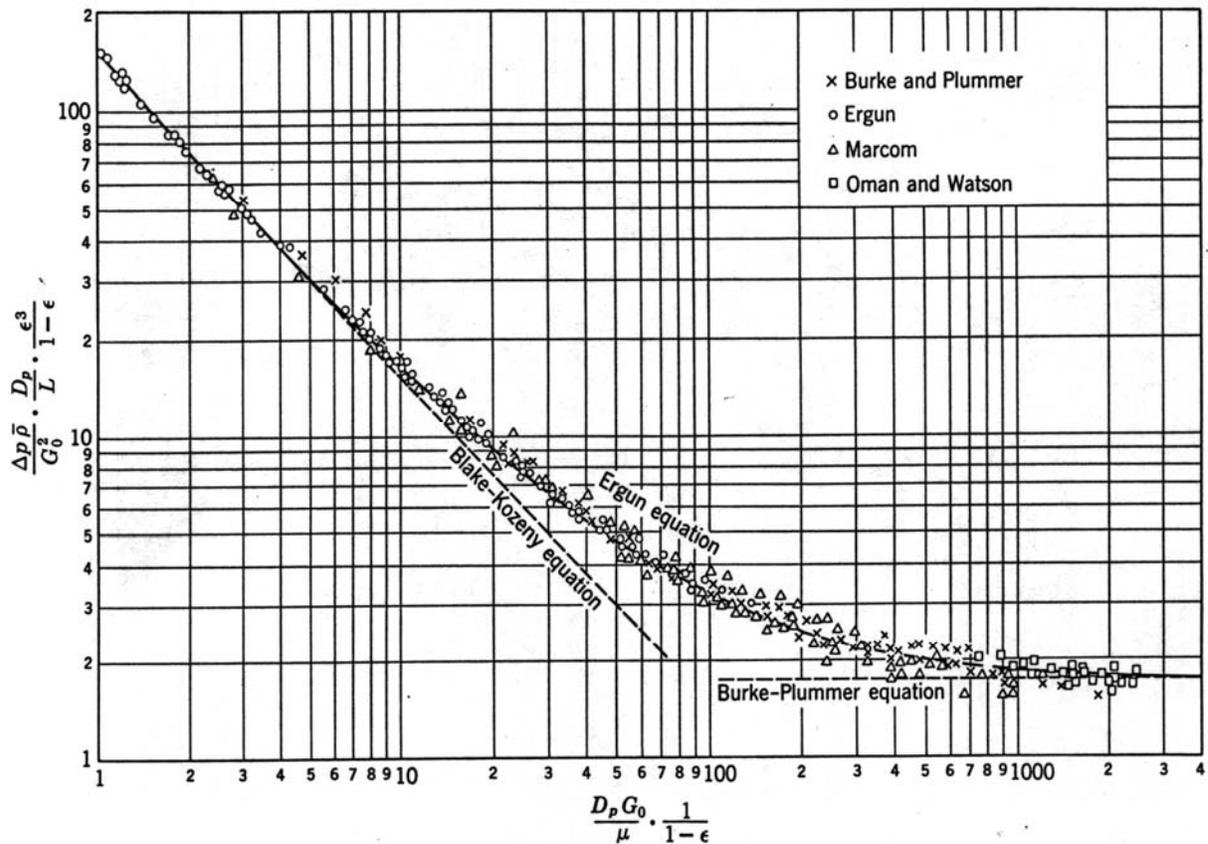

Figure 2.9 Friction factor vs. Reynolds number. This graph illustrates the correlation between Ergun and Blake-Kozeny at $Re_p < 10$; Ergun and Burke-Plummer equation at $Re_p > 1000$ [40].

As it can be seen from the graph, Ergun's equation does fit both the Kozeny-Carmen and Burke-Plummer models for their respective ranges, through laminar and turbulent flow, Ergun equation also models the frictional losses for Re_p between 10 and 1000 [96].

The friction factor is determined for the entire Reynolds number. For $Re_p < 10$ the flow through packed bed is laminar, the range $10 < Re_p < 1000$ is commonly referred to as transitional whereas flows characterized by $Re_p > 1000$ are considered turbulent [78].

Chapter Three

Fluid Flow Semi-Empirical Equations

3.1 Introduction

This chapter deals with achieving semi-empirical equations for modeling fluid flow through packed bed. The most important parameter in the equations is the pressure drop. The parameters affecting the pressure drop were taken from Ergun equation. A semi-empirical formula was achieved for the parameters affecting the pressure drop using Buckingham π theorem [80]. This formula consists of multiplied dimensionless terms raised to certain powers [81]; these powers were evaluated from experimental data taken from literatures with statistical fitting. The semi-empirical equations achieved can be divided into several types according to the packing system, mono size packing system, binary size packing system..., multi-sized packing system.

A semi-empirical equation is achieved for each type of packing referred to as a singular equation. An equation that can be used for all types of packing systems is called general equation. The shape of the singular and general equations are similar, the difference between them is in the constants used in the terms of these equations.

The second factor affecting the fluid flow through packed bed is the porosity of the packed bed. The porosity is included in the pressure drop equation. An empirical formula was achieved to evaluate the porosity for each type of packing using experimental data.

Singular and general semi-empirical equations achieved can be used within the fixed region of the fluid flow diagram; therefore, a semi-empirical equation

based on Leva equation [22] was written to evaluate the minimum fluidization velocity, in order to determine the working range of the written equations.

3.2 The Semi-Empirical Equations Model

The semi-empirical equations as written below depend on two main parameters, pressure drop and porosity.

The method of modeling used to derive an expression for the pressure drop was based on curve fitting of the available literatures experimental data by implementing dimensional analysis. This analysis can be summarized as follows:

The pressure drop was assumed to be dependent on fluid velocity (u), packing diameter (d_p), bed length (L), fluid density (ρ), fluid viscosity (μ), porosity (ϵ), and sphericity (ϕ), and can be written in the following expression:

$$\Delta P = f(u, d_p, L, \rho, \mu, \epsilon, \phi) \quad \dots (3.1)$$

The Buckingham's π theorem [80] was used to write the semi-empirical formula of the fluid flow equation. In this theorem the dimensions of a physical quantity are associated with mass, length and time, represented by symbols M, L and T respectively, each raised to rational powers [82]. The Buckingham's π theorem [80] forms the basis of the central tool of the dimensional analysis. This theorem describes how every physically meaningful equation involving n variables can be equivalently rewritten as an equation of $n-m$ dimensionless parameters, whereas, the number of fundamental dimensions used. Furthermore, and the most important is that it proves a method for computing these dimensionless parameters from the given variables [81]. According to this theorem $n=8$ and $m=3$, then this theorem gave us five dimensionless groups.

Table 3.1 The dimensions of parameters used in expression 3.1

Variable	Dimension
Pressure drop	$M L^{-1} T^{-2}$
Fluid velocity	$L T^{-1}$
Particle diameter	L
Bed length	L
Fluid density	$M L^{-3}$
Fluid viscosity	$M L^{-1} T^{-1}$
Porosity	-
Sphericity	-

Selecting the variables particle diameter, fluid velocity, and fluid density.

The particle diameter (d_p) has the dimension L therefore $L = d_p$

The fluid velocity (u) has dimensions $L T^{-1}$ therefore $T = d_p u^{-1}$

The fluid density (ρ) has dimensions $M L^{-3}$ therefore $M = \rho d_p^3$

The first group (π_1) = $\Delta P (M^{-1} L T^2)$

$$\pi_1 = \frac{\Delta P}{\rho u^2} \quad \dots (3.2)$$

The second group (π_2) = $L (L^{-1})$

$$\pi_2 = \frac{L}{d_p} \quad \dots (3.3)$$

The third group (π_3) = $\mu (M^{-1} L T)$

$$\pi_3 = \frac{\mu}{\rho u d_p} \quad \dots (3.4)$$

The fourth group (π_4) = ε

$$\pi_4 = \varepsilon \quad \dots (3.5)$$

The fifth group (π_5) = ϕ

$$\pi_5 = \phi \quad \dots (3.6)$$

Therefore the equation for the pressure drop dependence on fluid velocity (u),

packing diameter (d_p), bed length (L), fluid density (ρ), fluid viscosity (μ), porosity (ε), and sphericity (ϕ) will be as follows:

$$\frac{\Delta P}{\rho u^2} = b_1 \left(\frac{L}{d_p} \right)^{b_2} \left(\frac{\mu}{\rho d_p u} \right)^{b_3} \varepsilon^{b_4} \phi^{b_5} \quad \dots (3.7)$$

While Reynold number is defined as:

$$\text{Re} = \frac{\rho d_p u}{\mu} \quad \dots (3.8)$$

Then the equation (3.7) can be written as follows:

$$\frac{\Delta P}{\rho u^2} = b_1 \left(\frac{L}{d_p} \right)^{b_2} \left(\frac{1}{\text{Re}} \right)^{b_3} \varepsilon^{b_4} \phi^{b_5} \quad \dots (3.9)$$

Since $(\Delta P/\rho u^2)$ describes the fluid flow through packed bed, therefore; equation 3.9 can be considered as an empirical equation of fluid flow through packed bed. Each term of this equation is a dimensionless group, because $(\Delta P/\rho u^2)$ is dimensionless number.

3.3 The Porosity Formulas

The porosity is included in equation 3.9 as one of the main parameters. The porosity can be evaluated experimentally using the following equation [83]:

$$\varepsilon = 1 - \frac{\rho_b}{\rho_t} \quad \dots (3.10)$$

Where: ρ_t : is the true density of the particles, (g/cm^3)

ρ_b : is the apparent bulk density, (g/cm^3)

The porosity can be calculated theoretically using Furnas equation (3.11) [31]:

$$\varepsilon = 0.375 + 0.34 \frac{d_p}{D_R} \quad \dots (3.11)$$

Equation (3.11) is one of the simplest expressions that shows the dependence of packed bed porosity on particle diameter (d_p) and bed diameter (D_R).

Equation (3.11) can be modified to add a more accurate empirical formula for the porosity of equation (3.9). The new form of the suggested porosity depends on particle diameter and bed diameter. Experimental data were used to write the new form of the porosity which can be written in the following expression.

$$\varepsilon = \frac{b_1}{\left(b_2 D_R^{b_3} + b_4 d_p^{b_5}\right)^{b_6}} \quad \dots (3.12)$$

The constants of equation (3.12) can be evaluated from experimental data taken from literatures by using statistical fitting.

It will be seen in chapter 4 and chapter 5, that 13 equations of the same shape of equation 3.9 had been written, and used in the present work. The difference between these equations was in the rational powers raised to the different terms. There will be 6 singular equations for water flow through packed bed for the different types of packing (mono spherical particles, mono non spherical particles, binary spherical particles,...etc). There will be 5 singular equations for air flow through packed bed for the different types of packing (mono spherical particles, binary spherical particles,...etc). A general equation for water and a general equation for air flow through packed bed were also written and used. All these equations have there own porosity formulas. These equations of fluid flow and the porosity formulas were dependent on experimental data available from literatures.

3.4 Minimum Fluidization Velocity Semi-Empirical Equation

The acheived semi-empirical equation can be used for fluid flow up to the fluidization point. The minimum fluidization velocity is an indication for the fluidization point, therefore; the minimum fluidization velocity must be evaluated to find the fluidization point.

The experimental method for determining the minimum fluidization velocity is a graphical method by making two straight lines tangents to the pressure drop-velocity curve on either side of the fluidization point, the intersection of these lines denotes where fluidization occurs (u_{mf}) [84,85], as shown in figure below:

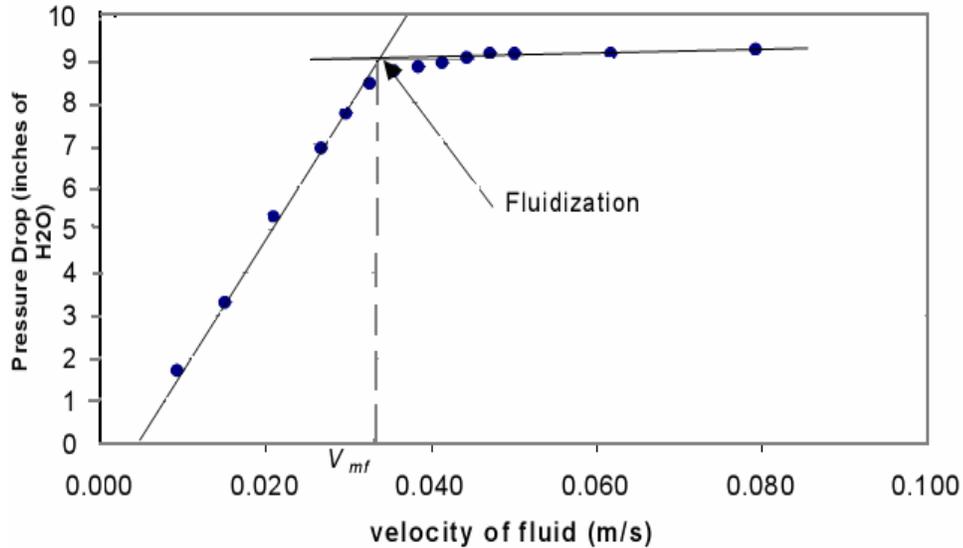

Figure 3.1 Standard plot of fluid velocity vs. pressure drop [110,85].

Leva [22] equation which is a semi-empirical equation for the prediction of minimum fluidization velocity could be used for fluidization in the gas phase only, which is written as follows:

$$u_{mf} = 0.0093 \frac{d_p^{1.82} (\rho_p - \rho)^{0.94}}{\mu^{0.88} \rho^{0.06}} \quad \dots (2.36)$$

For the fluidization in liquid phase a semi-empirical equation has been **acheived** based on the same form of **Leva** equation, by using experimental data from literatures for liquid phase, and making statistical fitting for this data. The semi-empirical equation is comparable with the Leva equation, and can be written as follows:

$$u_{mf} = 0.0878 \frac{d_p^{0.0048} (\rho_p - \rho)^{-0.0532}}{\mu^{0.0279} \rho^{0.1694}} \quad \dots (3.13)$$

Chapter Four

Results

The present chapter deals with the results of the achieved semi-empirical equations. These results depend on values of velocities, particles diameter, bed length and other parameters taken from experimental work. The results are divided into two main categories, water and air flow through packed bed. Each of the two categories was divided into subcategories. For each type of packing system, a semi-empirical equation was achieved. A general form of an empirical equation was achieved for multi sized of packing systems. Equations for each type of packing had been called singular. The equation of a multi sized had been called general equation.

4.1 The semi-empirical equations constants

Equation (3.9) derived in chapter three was fitted using experimental data obtained from literatures, in order to calculate the different constant in it. This had been done for water and air flow through packed bed of different types of packing. The resulted constants are presented in tables 4.1 and 4.2.

Table 4.1 Constants of equation 3.9 for water flow through packed bed

System type	b1	b2	b3	b4	b5

4.2 Studying the effect of different parameters on the semi-empirical general equation

This section shows the effect of different parameter on pressure drop using equation 3.9 after the substitution of the constants for the achieved general equation of multi-sized particle systems. The system includes all different types of packing systems (mono size spherical particles system, mono sized non spherical particles system, binary sized spherical particles system, ternary sized spherical particles system, quaternary sized spherical particles system, quinary sized spherical particles system).

A certain range for each parameter was taken in this study according to the available experimental data from literatures.

Most of the experimental previous works were studying the effect of different parameters of fluid flow on the pressure drop. So to get good comparison for the model form with the available experimental data, equation 3.9 have been multiplied by (ρu^2) . The new form of the equation will be a pressure drop equation.

The important parameters affecting the pressure drop in the equation was found to be particles diameter, porosity and bed length. The fluid velocity used was taken with in the fixed region.

The fluid physical properties used in all fluid flow equations were taken from experiments held at temperature of 32°C for air flow and 25°C for water flow through packed bed.

The effect of the different parameter on pressure drop has been studied and shown in the following subsections.

4.2.1 Water flow through packed bed

The effects of the different parameters are shown in fig.4.1 to 4.3.

4.2.1.1 Effect of particle diameter on pressure drop

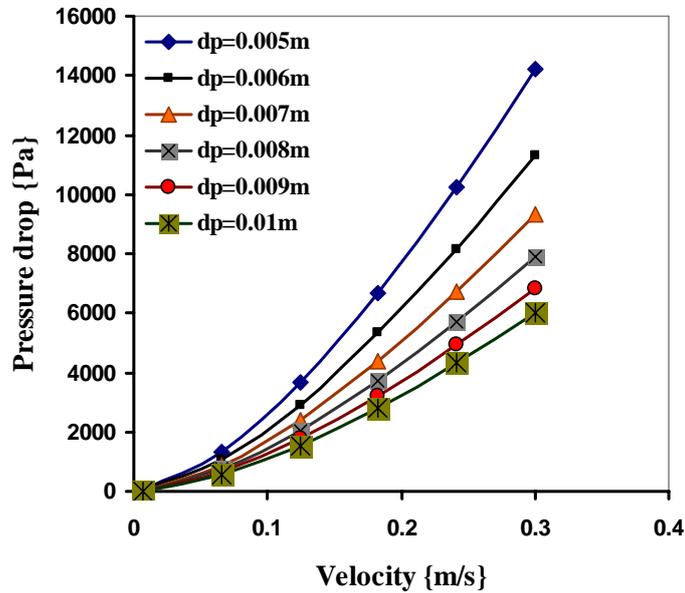

Figure 4.1 Pressure drop vs. velocity for the conditions bed diameter 0.08m, porosity 0.33, bed length 0.1m, at different particle diameters.

4.2.1.2 Effect of porosity on pressure drop

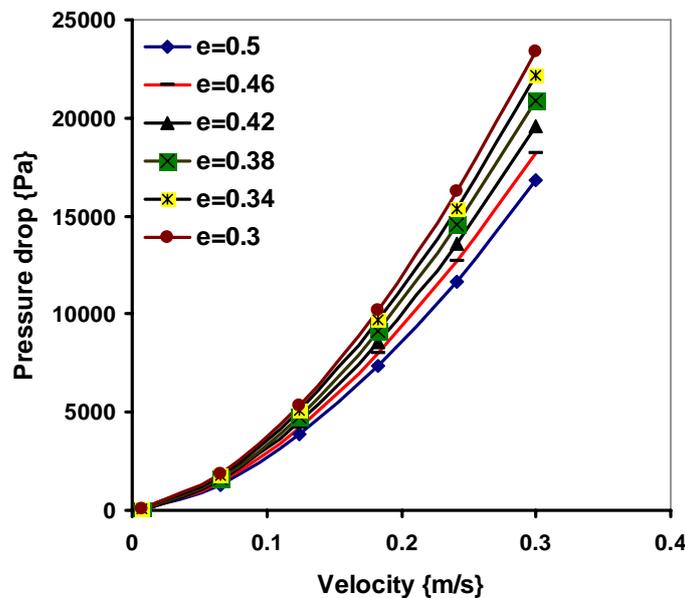

Figure 4.2 Pressure drop vs. velocity for the conditions bed diameter 0.08 m, particles diameter 0.005m, bed length 0.1m, at different porosities.

4.2.1.3 Effect of bed length on pressure drop

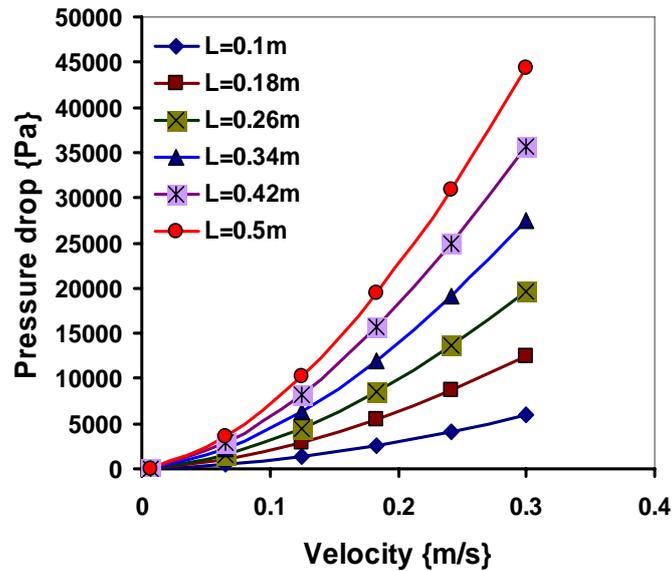

Figure 4.3 Pressure drop vs. velocity for the conditions bed diameter 0.08m, particles diameter 0.01m, porosity 0.33m, at different bed lengths.

4.2.2 Air flow through packed bed

The effects of different parameters are shown in figures 4.4 to 4.6.

4.2.2.1 Effect of particle diameter on pressure drop

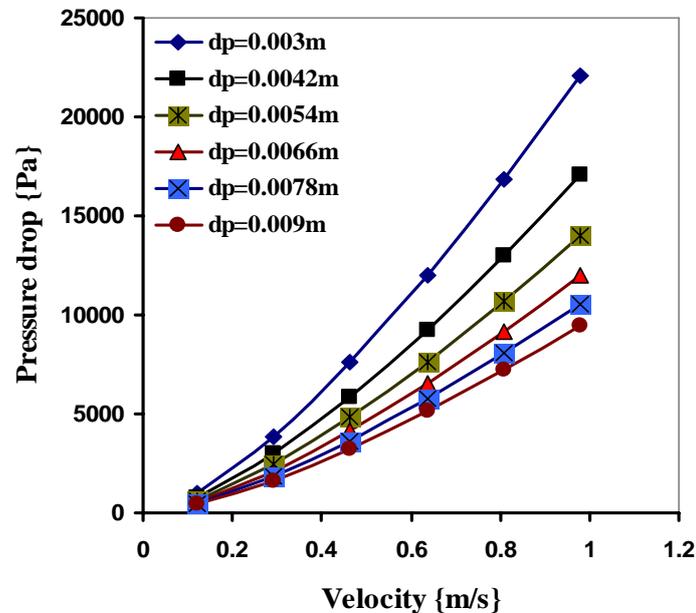

Figure 4.4 Pressure drop vs. velocity for the conditions bed diameter 0.07m, porosity 0.46m, bed length 0.1m, at different particle diameters.

4.2.2.2 Effect of porosity on pressure drop

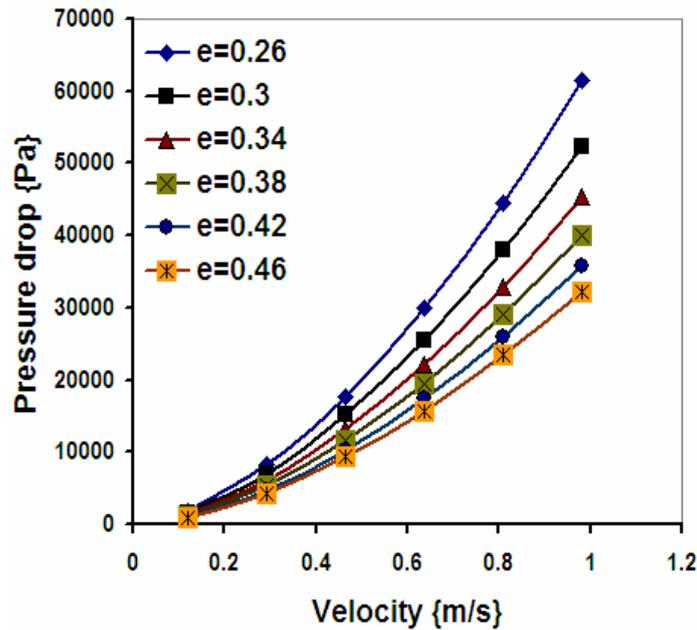

Figure 4.5 Pressure drop vs. velocity for the conditions bed diameter 0.07m, particle diameter 0.003m, bed length 0.1m, at different porosity.

4.2.2.3 Effect of bed length on pressure drop

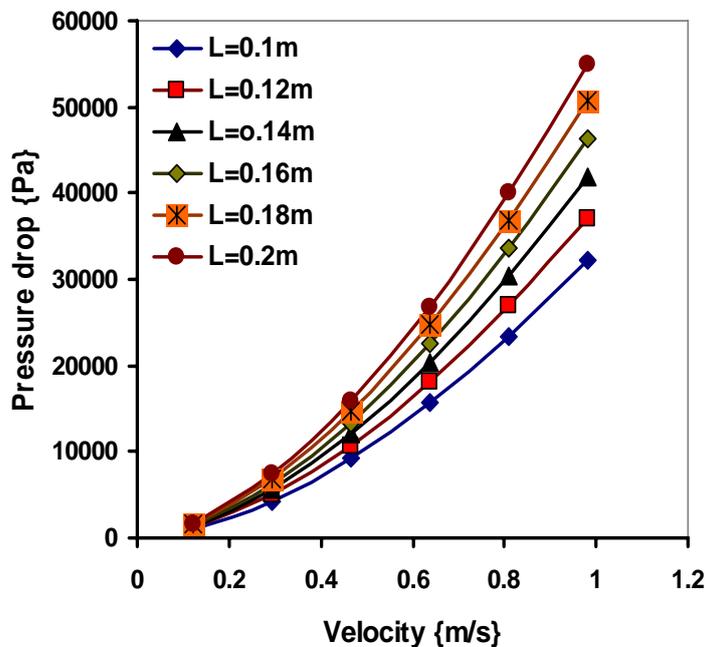

Figure 4.6 Pressure drop vs. velocity for the conditions bed diameter 0.07m, particle diameter 0.003m, porosity 0.46, at different bed length.

4.3 The porosity formula results of the fluid flow of the general equation

The porosity formulas written for the general equation have been tested. This test was with experimental data available and with theoretical calculation (equation 3.11). The results were shown in figures 4.7 and 4.8.

4.3.1 Water flow through packed bed

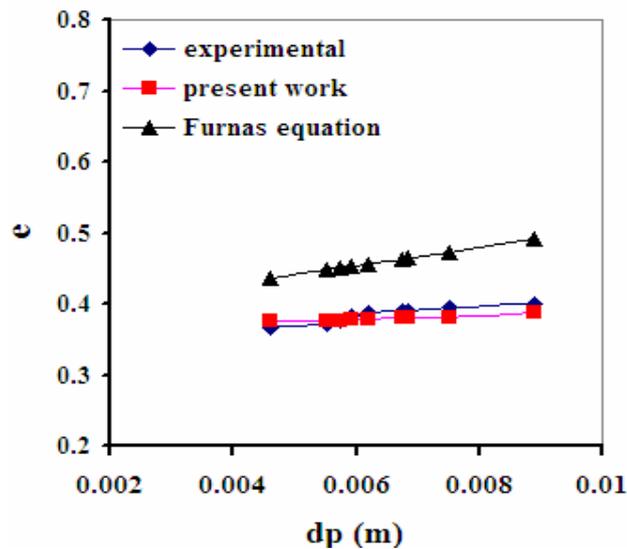

Figure 4.7 Porosity vs. particle diameter at bed diameter of 0.0764m.

4.3.2 Air flow through packed bed

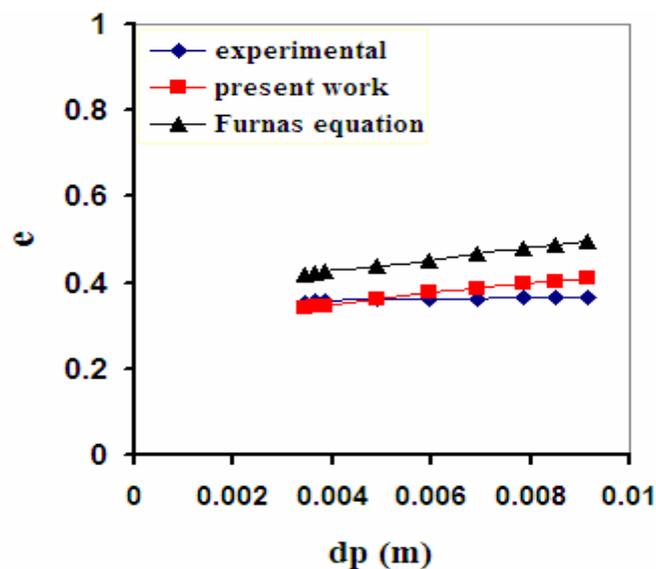

Figure 4.8 Porosity vs. particle diameter at bed diameter of 0.0764m.

4.4 Results of the minimum fluidization velocity equation

The results of the semi-empirical equation 3.13 are shown in the following table. This table show the parameters used in the equation from experiments. It also represents the experimental values for minimum fluidization velocity found in literatures.

Table 4.5 The minimum fluidization velocity results for water flow at room temperature (25°C)

4.5 Results for water flow through packed bed

4.5.1 Singular equations results for different types of packing

Tables 4.6 to 4.12 contain the calculation results of pressure drop through packed bed using equation (3.9). The constants of equation (3.9) were taken from table 4.1 for each type of packing system. The friction factor results were obtained from equation 2.39, and Reynold's number values were obtained from equation 2.40.

4.5.1.1 Mono size spherical particles system

4.5.2 General equation results

The following results are for the general equation for all systems considered in the present work. The general equation constants are shown in table 4.1. Tables 4.12 to 4.17 below represents the results of pressure drop through packed bed by using the general equation for (mono size spherical particles system, mono sized non spherical particles system, binary sized spherical particles system, ternary sized spherical particles system, quaternary sized spherical particles system and multi sized spherical particles system, respectively). The friction factor results were obtained from equation 2.39, and Reynolds number values were obtained from equation 2.40.

4.6 Results of air flow through packed bed

4.6.1 Singular equations results for different types of packing

Tables 4.18 to 4.22 represent the calculation results of pressure drop through packed bed of spherical particles using equation (3.9). The constants of equation (3.9) were taken from table 4.2 for each type of packing system. The friction factor results were obtained from equation 2.39, and Reynolds number values were obtained from equation 2.40.

4.6.1.1 Mono size spherical particles system

4.6.2 General equation results

The following results are for the general equation for all systems considered in the present work. The general equation constants are shown in table 4.2. Tables 4.23 to 4.27 below represents the results of pressure drop through packed bed by using the general equation for (mono size spherical particles system, binary sized spherical particles system, ternary sized spherical particles system, quaternary sized spherical particles system and multi sized spherical particles system, respectively). The friction factor results were obtained from equation 2.39, and Reynolds number values were obtained from equation 2.40.

Chapter Five

Discussion

This chapter contains the discussions of the achieved equations results, and the comparisons between these results and experimental results taken from literatures, as well as comparisons were made between all these results and similar results taken by using Ergun equation for air and water flow through packed bed. The results are classified into two categories according to the fluid used, i.e. water and air flow through packed bed.

5.1 General equation results

5.1.1 Water flow through packed bed

5.1.1.1 Effect of particle diameter on pressure drop

Figure 4.1 indicates that an increase in the particle diameter causes decrease in the pressure drop, this is due to the fact that when the particle diameter increase's the specific surface area decreases according to equation (2.2), the reason of this relation is that when the surface area decreases the resistance of fluid flow decreases which leads to a decrease in pressure drop. (The pressure drop inversely proportional to particles diameters)[52]. For example at velocity 0.3 m/s when the particle diameter is 0.01m the pressure drop is 5.994 Kpa, while for the same velocity with particle diameter of 0.005m the pressure drop is 14.196 Kpa.

5.1.1.2 Effect of porosity on pressure drop

Figure 4.2 shows that when the porosity increases the pressure drop decreases, where the void fraction between particles become larger this leads to less resistance to fluid flow through the bed [84]. For example at velocity

0.3 m/s when the porosity is 0.5 the pressure drop is 16.797 Kpa, while for the same velocity with porosity of 0.3 the pressure drop is 23.373 Kpa .

5.1.1.3 Effect of bed length on pressure drop

Figure 4.3 show that whenever the length of the packing height increases the fluid flow resistance increases this leads to an increase in pressure drop, as shown by the work of Coluson 1949[34]. For example at velocity 0.3 m/s when the packing height is 0.1m the pressure drop is 5.9941Kpa, while for the same velocity with packing height of 0.26 m the pressure drop increased to 19.6516 Kpa, further increase in the packing height to 0.5 m for the same velocity the pressure drop increased to 44.3828 Kpa.

5.1.2 Air flow through packed bed

5.1.2.1 Effect of particle diameter on pressure drop

Figure 4.4 shows that the increase in the particle diameter causes decrease in the pressure drop this is due to the specific surface area as shown in equation (2.2). Where smaller particle diameter used, i.e. more particles numbers, leads to less voids in the packed bed and an increased surface area resisting the fluid flow this will increase the pressure drop (the pressure drop inversely proportional to particles diameters) [55]. For example at velocity 0.98 m/s when the particle diameter is 0.009m the pressure drop is 9452.2688 pa, while for the same velocity with particle diameter of 0.003m the pressure drop is 22112.4602 pa .

5.1.2.2 Effect of porosity on pressure drop

Figure 4.5 show that the pressure drop in the bed is inversely proportional to bed porosity for the same velocity of the fluid entering the bed [92], this is due to the fact that when the void fraction between particles becomes larger this leads to less resistance to fluid flow through the bed. For example at velocity 0.98 m/s

when the porosity is 0.46 the pressure drop is 32.195 Kpa, while for the same velocity with porosity of 0.26 the pressure drop increased to 61.399 Kpa .

5.1.2.3 Effect of bed length on pressure drop

Figure 4.6 show that when the length of the packing height increases the fluid flow resistance increase and this is leads to an increase in pressure drop [34]. For example at velocity of 0.98 m/s when the packing height is 0.1m the pressure drop is 32.195 Kpa, while for the same velocity with packing height of 0.2 m the pressure drop increased to 55.039 Kpa.

5.2 The porosity formula of the general equation

The porosity formula used in the achieved semi-empirical equations has been tested as shown in figures 4.7 and 4.8, for water and air flow respectively. This test was by comparing the results of this formula with results of experimental data and theoretical calculations (Furnas equation [31]). The comparisons show a very good agreement between the porosity formula results (equation 3.12) and the experimental data, while Furnas equation of porosity was far away from the experimental data. So the written porosity formula can be used with confidence with any type of packing system.

5.3 The minimum fluidization velocity equation

The results of the semi-empirical equation for the minimum fluidization velocity for water flow through packed bed (equation 3.13) are shown in table 4.5. The table also shows experimental values of minimum fluidization velocity taken from literatures [54, 60, 86, 87, 93, 94, 99, 101]. From this table, it can be seen that the values of the minimum fluidization velocity of the semi-empirical model used are comparable with the experimental values of the minimum

fluidization velocity for water flow. So the ranges of calculations for water flow in the achieved equations were taken to be not exceeding this minimum value of velocity.

Leva equation [22] for air flow through packed bed was used because there are not available literatures data for minimum fluidization velocity for air flow, besides the data used for air was within the fixed region only.

5.4 Comparisons between achieved equations, Ergun equation and experimental results for water flow through packed bed

5.4.1 Singular equations results for different types of packing

5.4.1.1 Mono size spherical particle system

The values of pressure drop versus velocity for water flow through packed beds of mono size particles were plotted in figures 5.1a, 5.2a, 5.3a and 5.4a. The values of friction factors versus Reynolds numbers were plotted in figures 5.1b, 5.2b, 5.3b and 5.4b.

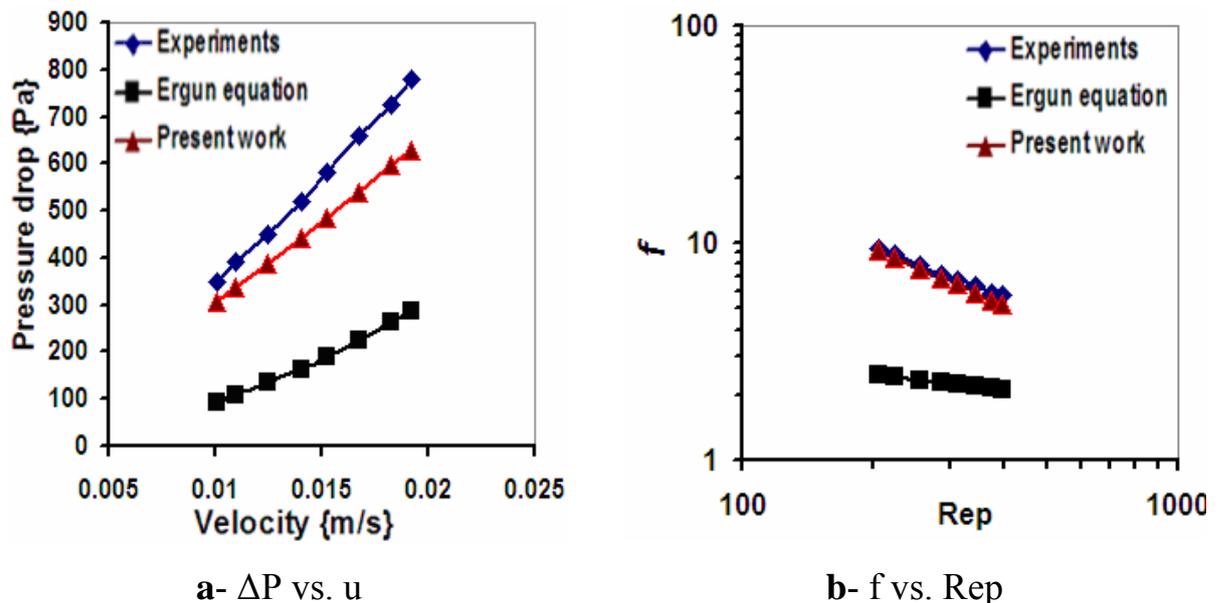

Figure 5.1 a- Pressure drops vs. velocity, b- Friction factor vs. Reynolds number for pea gravel of particles diameter 1.27cm, bed porosity of 0.393, packing height of 41.28cm, bed diameter of 8.89cm[87] (Table 4.6)

expected because of changing the properties of the packing materials leads to large effect on Ergun equation's prediction of pressure drop [85]. In the achieved equation several types of packing were used, which is Pea Gravel, Marbles, Glass Marbles, Black Marbles, Clear Marbles, Acrylic balls and Glass spheres.

Figures 5.1b, 5.2b and 5.3b show that the achieved equation results of friction factor-Reynold's number curve is close to the values of friction factor-Reynolds number curve of the experimental results. The values of friction factor of modified model results (range from 9.27-5.25, 5.96-4.02 and 9.61-4.62 respectively) are close to those of experimental data results (range from 9.42-5.76, 6.13-3.94 and 10.14-4.44 respectively), for Reynolds numbers (range from 206.03-393.34, 238.57-393.12 and 127.99-293.44 respectively). This means that the achieved equation is very close to the experimental results.

The wall affect on bed porosity increases the porosity, this appears clear in figures 5.1 and 5.2 where the bed porosity increased to a value of 0.393, while the bed diameter is (8.89cm), and the particle diameter is (1.27cm). The effect of wall on porosity may be due to the reduction in the ratio of bed diameter to particle diameter than the supposed ratio ($(D_R/d_p) \geq 10$) [31].

For large particles in small column (Fig.5.4), the wall presents an artificial boundary that alters the void fraction, which appears to be smaller than its true value, and the data appears lower than its true value [95].

The achieved equation (3.9) was fitted for water flow through packed beds of mono-sizes spherical particles. In this fitting 40 sets of data from the literature[3,9,20,28,54,84,85, 86,87,93, 94,96, 97,98,100, 101,102,103,104] were used. In these sets 396 values of pressure drop versus velocity were taken. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 230840.9 \left(\frac{L}{d_p} \right)^{0.8302} \left(\frac{1}{\text{Re}} \right)^{0.8815} \varepsilon^{-3.0274} \phi^{0.1} \quad \dots (5.1)$$

The average percentage error was found to be 4.8397% between experimental work and the achieved equation.

The porosity used in the presented model was evaluated from best fitting of experimental data of water flow through packed beds of mono-sizes spherical particles. This porosity is represented in the following equation.

$$\varepsilon = \frac{0.0624}{\left(0.2125 D_R^{0.0566} - 0.1803 d_p^{0.01096}\right)^{0.4625}} \quad \dots (5.2)$$

The above correlation deviate's from experimental with a very small average percentage error of $6.11682 \cdot 10^{-8} \%$. This means that they are identical.

In the following figure a comparisons between present model and experimental data [60, 89, 90, 101, 106], which is not included in the fitting of the present model are presented. These have been done to check that equation 5.1 could be working for different conditions. Figure 5.4 are presented below, while other comparisons are presented in appendix A (A.9 and A.10)

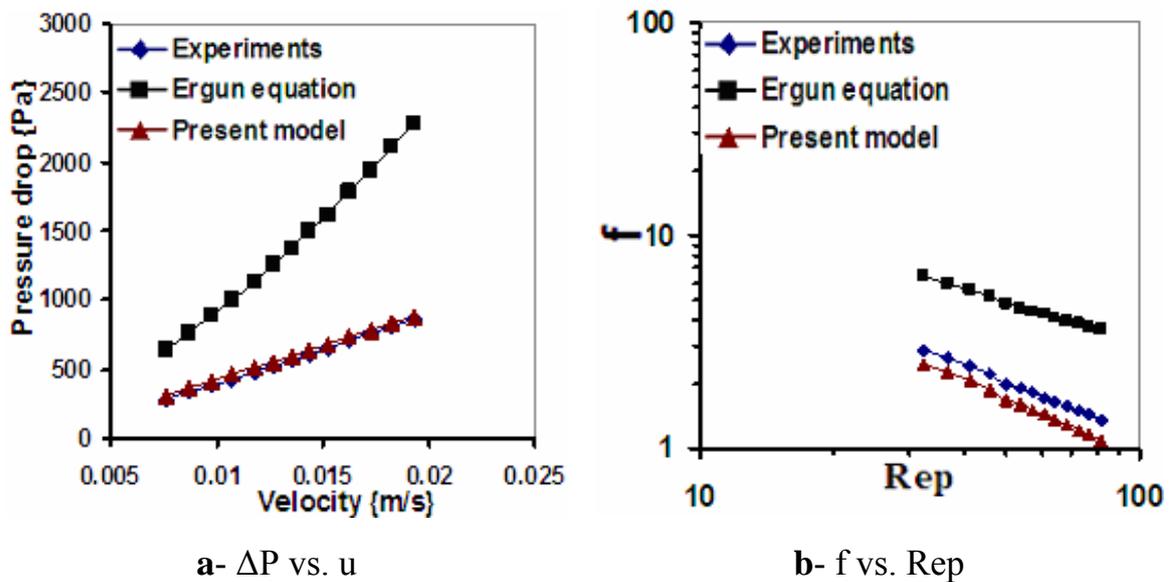

Figure 5.4 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for pea gravel spherical particles diameter of 0.26, bed porosity of 0.3615, packing height of 41.21cm, bed diameter of 8.26cm [106] (Appendix A.8)

Although these figures are not included in the modeling they show a very good agreement with experimental data [60, 101, 106, 89, 90].

5.4.1.2 Mono size non spherical particles system

The values of pressure drop for mono size non spherical particles versus velocity were plotted in figures 5.5a, and 5.6a. The values of friction factors versus Reynolds numbers were plotted in figures 5.5b and 5.6b.

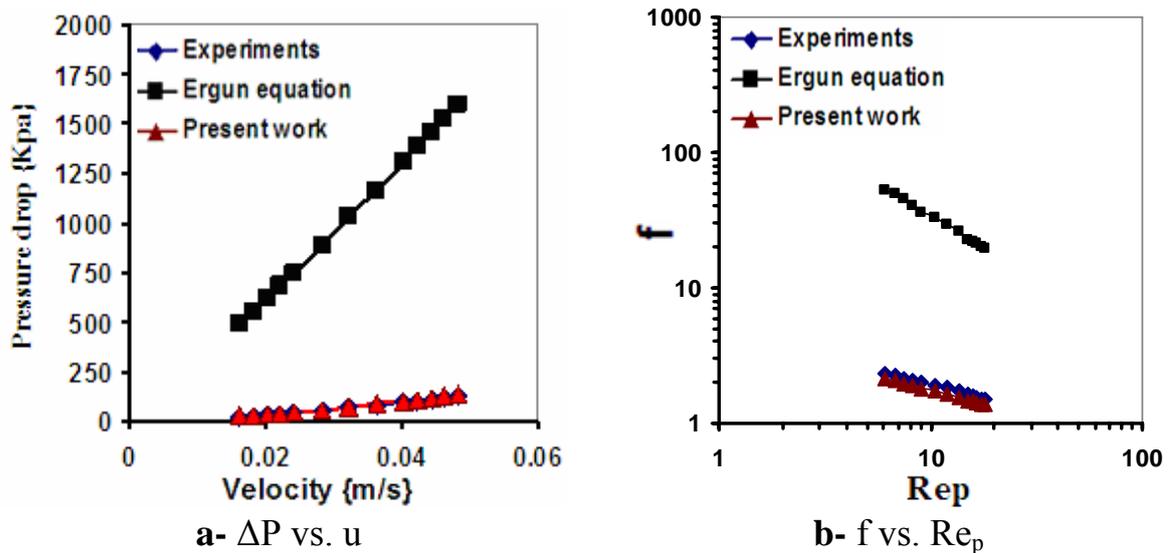

Figure 5.5 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for pea gravel of particle diameter 0.0254cm, sphericity of 0.7, bed porosity of 0.3064, packing height of 43.18cm, bed diameter of 8.89cm [54] (Table4.7)

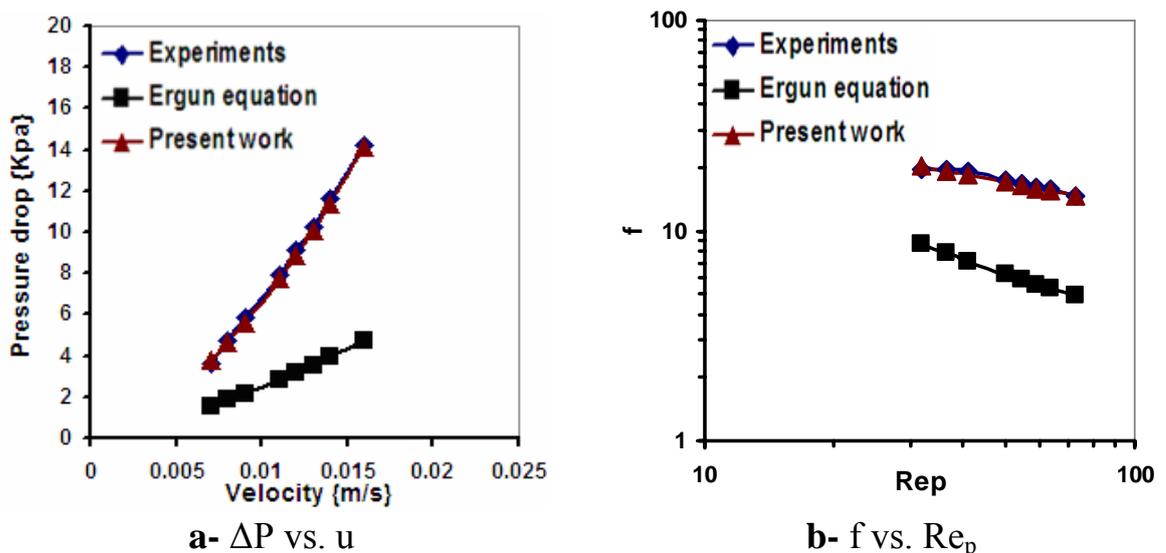

Figure 5.6 a-Pressure drop vs. velocity , b-Friction factor vs. Reynolds numbers for rasching rings of particles diameter 0.3cm,sphericity of 0.85, bed porosity of 0.3538,packing height of 67.3cm, bed diameter of 8.89cm [93](Appendix A.11)

Similar comparisons between experimental data and the achieved equation are shown in appendix A (A.12 to A.15).

The above figures show that the achieved equation gave a good fitting to the experimental data rather than Ergun equation. This appears clear in figure 5.6, which shows that the model results of pressure drop-velocity curves coincide with experimental results, while the results from Ergun equation lie above them. The deviation of Ergun curves for rasching rings may be for the reason that Ergun equation was not tested on object with holes (Sabri Ergun did not limit his experiment to spherical packing. He tested his theory with cylinders, tablets and crushed materials, but did not test it with objects with holes [5,46]).

Figure 5.5a show that the achieved results of pressure drop-velocity curve lie on the experimental results curve. The values of pressure drop of the model results in figure 5.5a (range from 22.69 to 131.5 kpa) are close to those of experimental data results (range from 21.95 to 129.39 kpa), for velocity (range from 0.016 to 0.048). The same is seen in figure 5.5b which shows that the model results of friction factor-Reynolds number curve lie on the experimental results. The values of friction factor of figure 5.5b (range from 2.131 to 1.372) are close to those of experimental data results (range from 2.303 to 1.393), for Reynolds numbers (range from 6.021 to 18.06). This means that the achieved equation is very close to the experimental results.

Equation 3.9 was fitted for water flow through packed beds of mono-sizes non spherical particles. In this fitting 18 sets of data from literatures [1, 54, 93, 94, 99, 100, 101, 105] were used, which includes 150 values of pressure drop versus velocity. So, the singular form of the achieved semi-empirical equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 3641.207 \left(\frac{L}{d_p} \right)^{0.7670} \left(\frac{1}{\text{Re}} \right)^{0.4006} \varepsilon^{-3.1935} \phi^{0.9310} \quad \dots (5.3)$$

The largest average percentage error was found to be 6.8548% between experimental work and the achieved equation, while the average percentage error between the experimental work and the achieved equation was found to be 5.1117% for the calculations in set one and two [54] which were for packing type of pea gravel with shape factor of 0.7.

The porosity used in the presented model was proposed from best fitting of experimental data of water flow through packed beds of mono-sizes spherical particles. This porosity is represented in the following equation:

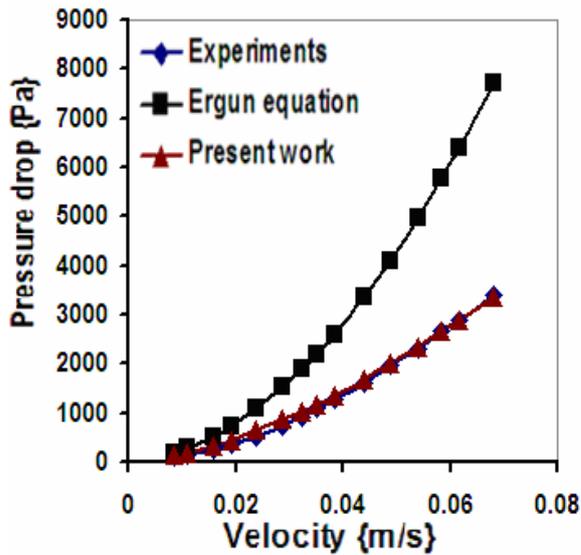

$$\varepsilon = \frac{0.0302}{\left(0.0014 D_R^{-0.2784} + 0.0125 d_p^{-0.097}\right)^{0.6634}} \quad \dots (5.4)$$

The above equation deviates from experimental with a small average percentage error of 0.38895 %.

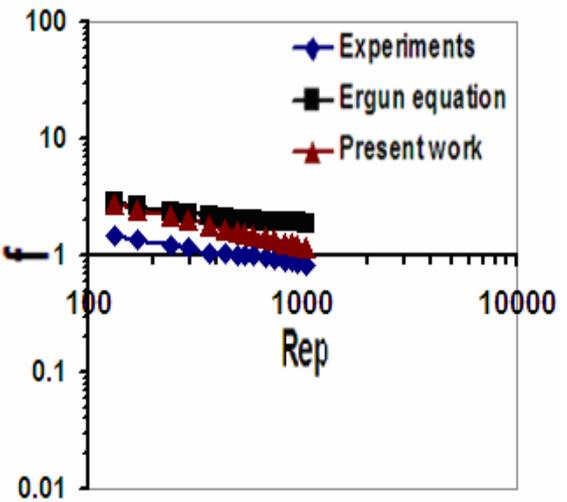

The average percentage error between the experimental work and the achieved equation in mono non spherical packing system was found to be higher than that of mono spherical packing system (6.8548% for mono non spherical packing system and 4.8397% for mono spherical packing system). This is because in mono size system the shape factor (sphericity) is always one in all spherical particles while in mono non spherical particles system the shape factor (sphericity) is changeable according to the packing type from (0-1) in different experiments .The values (0.3 -0.9) for sphericity were used because data for these values are available in literatures [1, 54, 93, 94, 99, 100, 101, 105].

5.4.1.3 Binary sized spherical particles system

The values of pressure drop for water flow through packed beds of binary sized spherical particles were plotted versus velocity in figures 5.7a, 5.8a and 5.9a. The values of friction factors versus Reynolds numbers were plotted in figures 5.7b, 5.8b and 5.9b.

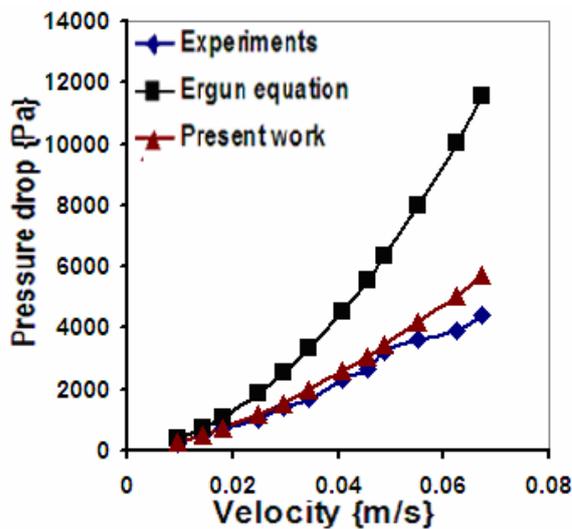

a- ΔP vs. u

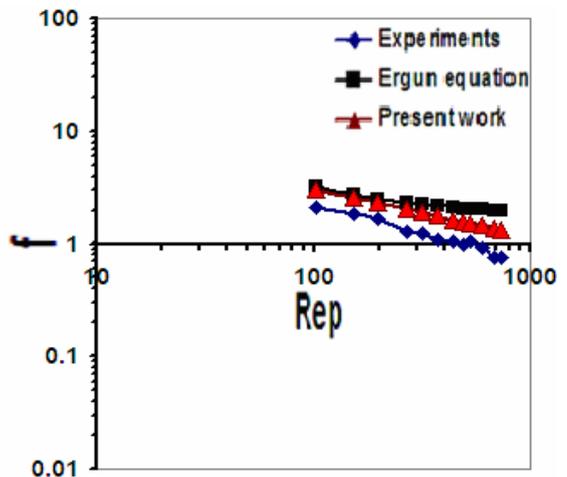

b- f vs. Re_p

Figure 5.7 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for Acrylic balls of particles diameter ($dp_1=0.655$ cm, $dp_2=1.27$ cm, with $dp_{eff}=1.016$ cm), fractions of ($x_1=0.25, x_2=0.75$), bed porosity of 0.367, packing height of 49.53 cm, bed diameter of 8 cm[88] (Table 4.8)

a- ΔP vs. u

b- f vs. Re_p

Figure 5.8 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for Acrylic balls of particles diameter ($dp_1=0.655$ cm, $dp_2=1.27$ cm, with $dp_{eff}=0.7257$ cm), fractions of ($x_1=0.75, x_2=0.25$), bed porosity of 0.3612, packing height of 50.8 cm, bed diameter of 8 cm[107] (Appendix A.16)

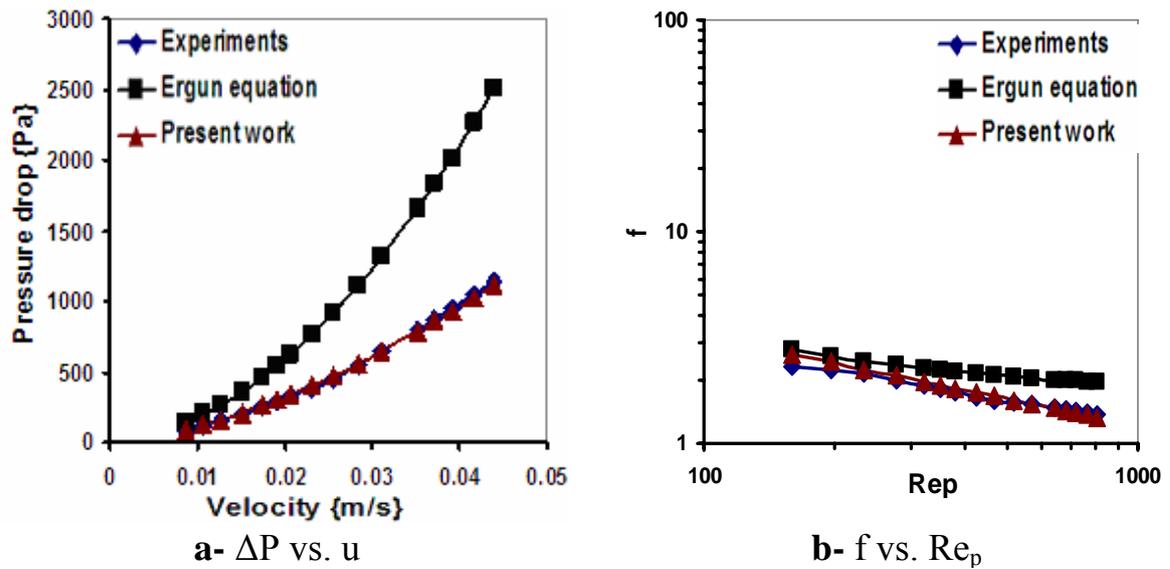

Figure 5.9 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for Acrylic balls of particles diameter ($dp_1=0.655\text{cm}$, $dp_2=1.27\text{cm}$, with $dp_{\text{eff}}=0.7257\text{cm}$), fractions of ($x_1=0.75, x_2=0.25$), bed porosity of 0.3612, packing height of 40.64cm, bed diameter of 8cm[107] (Appendix A.17)

Similar comparisons between experimental data and achieved equation are shown in appendix A (A.18 to A.22).

The achieved equation gave a good fitting to the experimental data rather than Ergun equation; this is because Ergun's equation is based on a large ratio of column diameter to particle diameter, neglecting wall effect. (In order to neglect wall effects a ratio of 10 or greater should be used [108]). While figure 5.7 show that the ratio of bed diameter to particle diameter is (8/1.016) which is less than 10. Ergun equation neglects wall effects which cause a great difference from experimental results. The wall effects is included in all experiments, also the present model includes this effect through the equation constants.

The most noticeable effect for mixing two sizes of particles is the decrease in porosity with respect to mono sized particles. This is because in binary system the particles with smaller sizes tend to fill the voids between the larger sizes particles [109].

Figure 5.8 and 5.9 show that as the packing height increases the pressure drop increases, this is because when the packing height increases the fluid flow resistance increases and this leads to an increase in the pressure drop. The packing height increased from 40.64 cm (Fig. 5.9) to 50.8cm (Fig. 5.8), which led to increase the pressure drop values from the range of (85.767-1117.4) Pa (Fig 5.9), to the range of (257.38-5704.8) Pa (Fig 5.8), for the same porosity of 0.3612, bed diameter of 8cm, effective particle diameter of 0.7257cm.

Equation (3.9) was fitted for water flow through packed beds of binary sized spherical particles. In this fitting 26 sets of data were used [88, 89, 90, 91, 107], which include 350 values of pressure drop versus velocity. So, the singular form for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 41.7922 \left(\frac{L}{d_p} \right)^{1.121} \left(\frac{1}{\text{Re}} \right)^{0.4194} \varepsilon^{-0.2435} \phi^{0.1} \quad \dots (5.5)$$

The average percentage error was found to be 1.1807% between experimental work and the achieved equation.

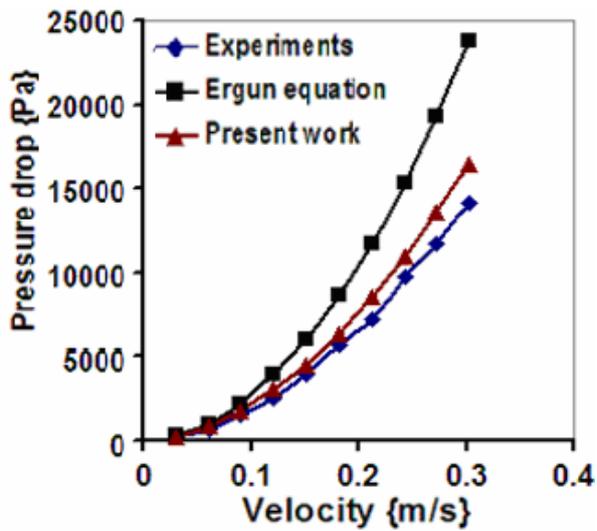

The porosity used in the present model was evaluated from best fitting of experimental data of water flow through packed beds of binary-sizes spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{0.0161}{\left(1.8949 D_R^{0.8813} - 0.1864 d_p^{0.0342} \right)^{0.987}} \quad \dots (5.6)$$

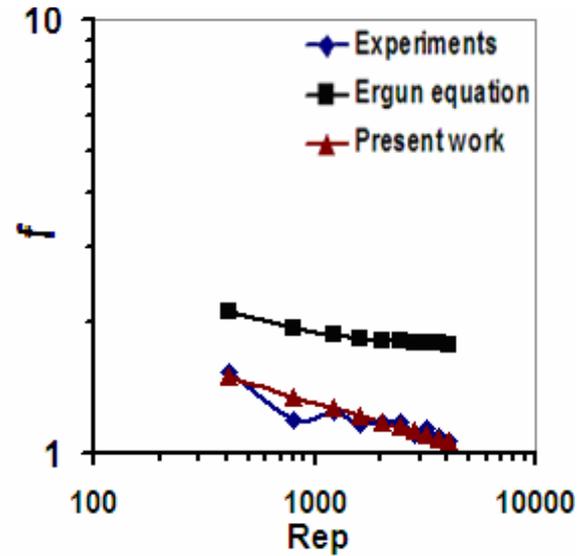

The above equation deviates from experimental with an average percentage error of 0.00577 %.

5.4.1.4 Ternary sized spherical particles system

The values of pressure drop for water flow through packed beds of ternary sized spherical particles versus velocity were plotted in figures 5.10a, 5.11a and 5.12a. The values of friction factors versus Reynolds numbers were plotted in figures 5.10b, 5.11b and 5.12b.

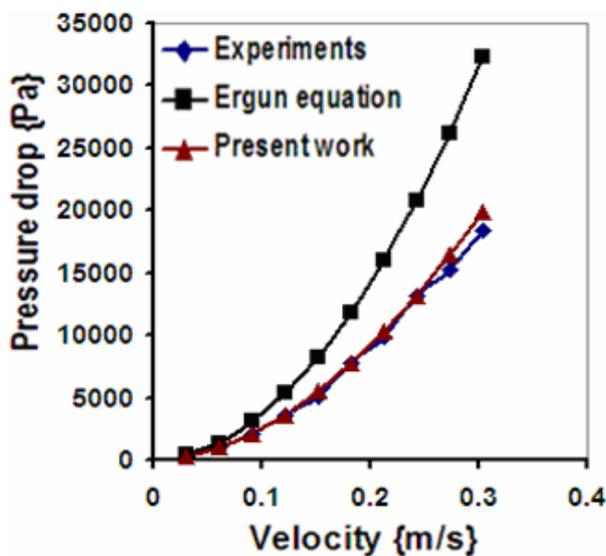

a- ΔP vs. u

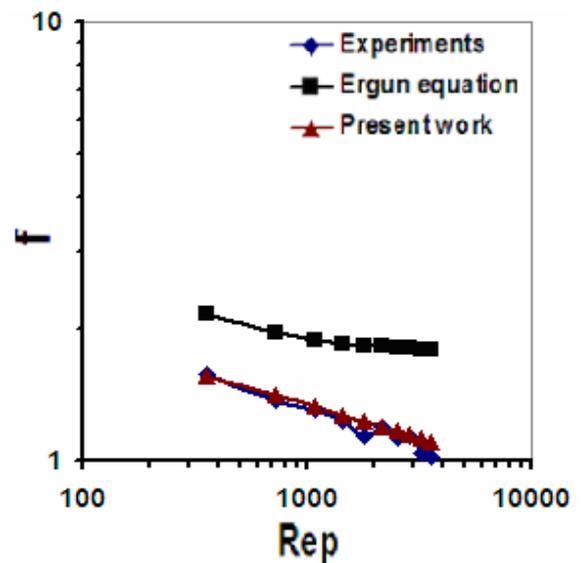

b- f vs. Re_p

Figure 5.10 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass of particles diameter ($dp_1=0.9987$, $dp_2=0.7955$ and $dp_3=0.6015$ cm ,with $dp_{eff}=0.765$ cm), bed porosity of 0.4111, packing height of 15.15cm, bed diameter of 7.62 cm [89] (Table 4.9)

a- ΔP vs. u

b- f vs. Re_p

Figure 5.11 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for spherical particles diameter of ($dp_1=0.9987$, $dp_2=0.7955$ and $dp_3=0.509$ cm, with $dp_{eff}=0.71$ cm), bed porosity of 0.4023, packing height of 15.15 cm, bed diameter of 7.62 cm [89] (Appendix A.23)

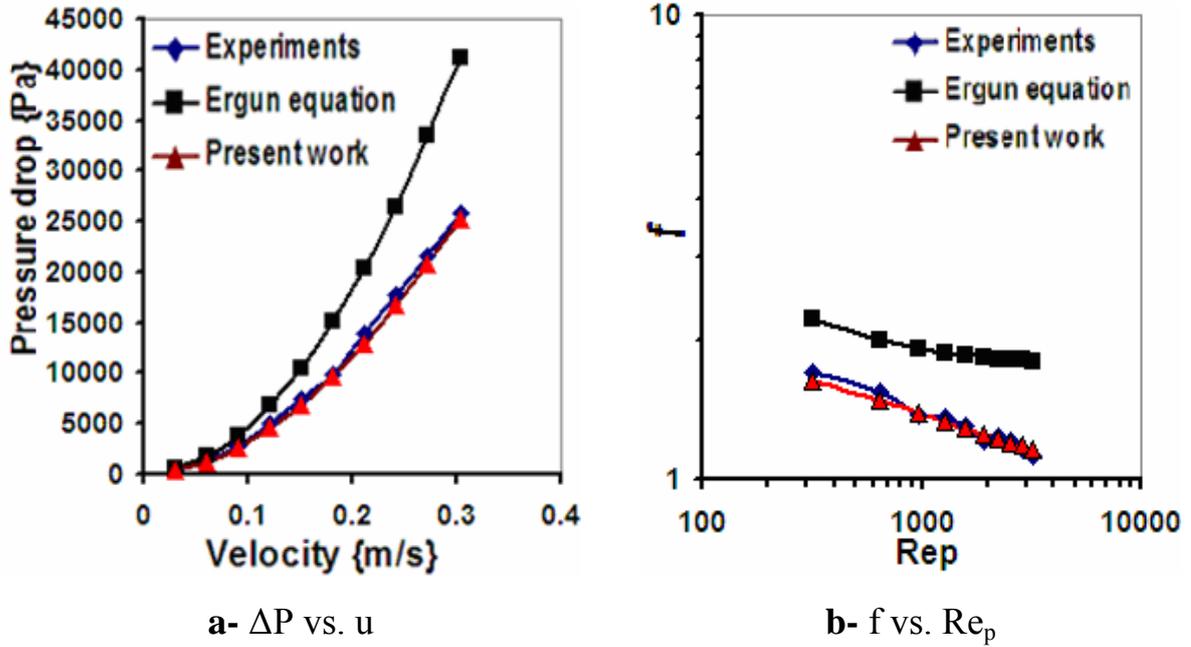

Figure 5.12 a-pressure drop vs.velocity, b-Friction factor vs. Reynolds numbers for spherical particles diameter of ($dp_1=0.9987$, $dp_2=0.7955$ and $dp_3=0.421$ cm, with $dp_{eff}=0.647$ cm), bed porosity of 0.3921, packing height of 15.15 cm, bed diameter of 7.62 cm [89] (Appendix A.24)

Similar comparisons between experimental data and achieved equation are shown in appendix A (A.25 to A.31)

The above figures show that, the modified model gave a good fit to the experiment rather than Ergun equation, the reason of this difference may lie on the basis of Ergun equation itself [101, 77].

Equation (3.9) was fitted for water flow through packed beds of ternary sized spherical particles. In this fitting 25 sets of data [107, 88, 89, 90] were used. In these sets 250 values of pressure drop versus velocity were taken. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 0.3343 \left(\frac{L}{d_p} \right)^{0.9829} \left(\frac{1}{Re} \right)^{0.1480} \varepsilon^{-5.0567} \phi^{0.1} \quad \dots (5.7)$$

The average percentage errors were found to be 5.5858% between experimental work and the achieved equation.

The porosity used in the presented model was proposed from best fitting of experimental data of water flow through packed beds of ternary-sizes spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{0.0380}{\left(2.0945D_R^{-0.0569} - 2.4662d_p^{0.0099}\right)^{0.9163}} \quad \dots (5.8)$$

The above correlation deviates from experimental with an average percentage error of 0.00033 %.

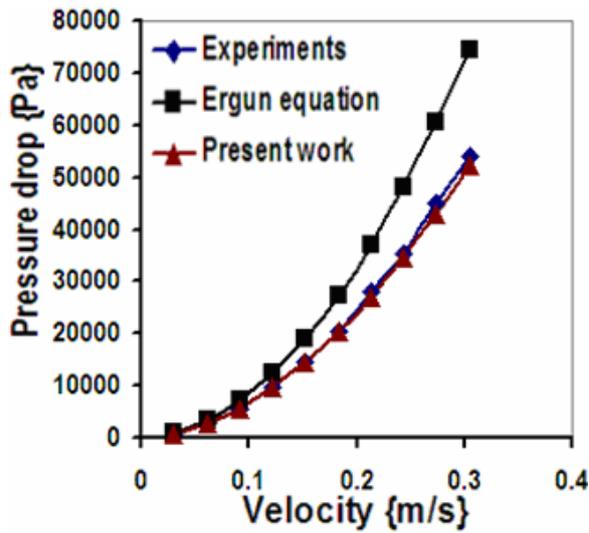

It can be noticed that the porosity of ternary sized packing are generally close to each other, since the voids could be filled with different sizes of particles [12].

The bed porosity highly affects the pressure drop and inversely proportional to it [104], this is appeared in figure 5.10a .This figure shows that for bed porosity of 0.411075 the pressure drop value has a range from 232.001 to 16498.5 Pa, which is less than the range of figure 5.11a for larger value of bed porosity of 0.4023, where the pressure drop values range from 280.459 to 19944.5 Pa.

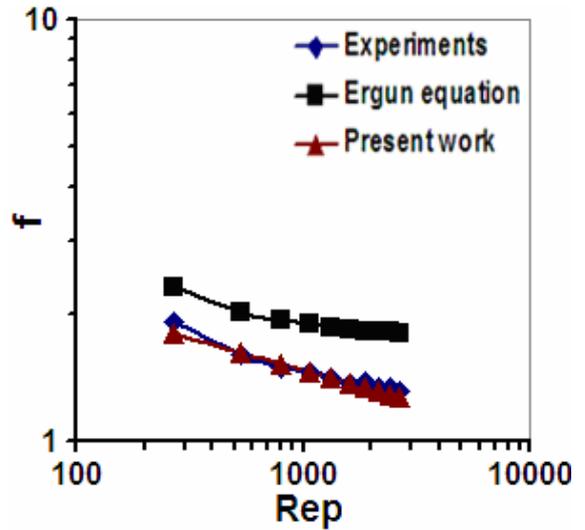

In all figures, it can be noticed that the divergence values of friction factor is at low values of Reynolds number (laminar and transition region) but its convergence at high values of Reynolds number (turbulent region), because in the turbulent region where the high rate velocity of fluid behaves as a slip velocity and has insignificant effect on the friction values [100,101].

5.4.1.5 Quaternary sized spherical particles system

The values of pressure drop for water flow through packed beds of quaternary sized spherical particles versus velocity were plotted in figures 5.13a, and 5.14a. The values of friction factors versus Reynolds numbers were plotted in figures 5.13b and 5.14b.

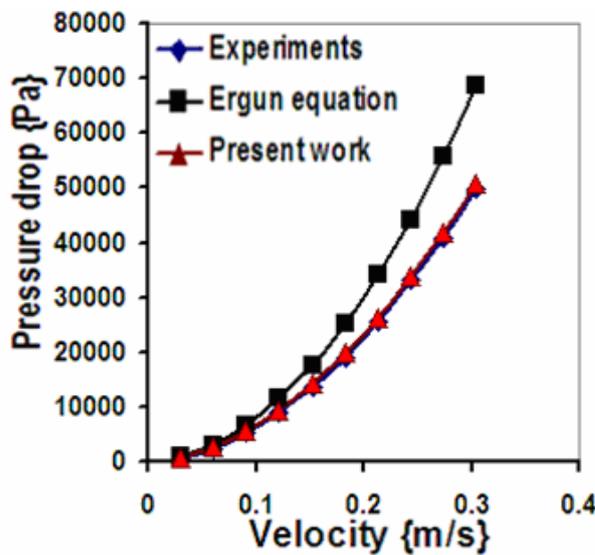

a- ΔP vs. u

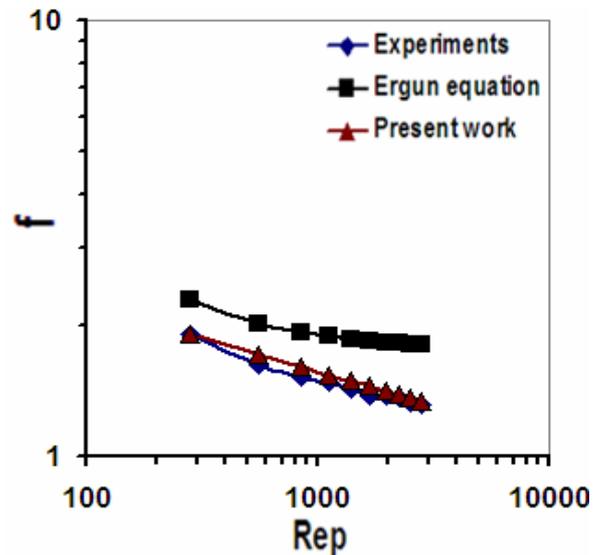

b- f vs. Re_p

Figure 5.13 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for spherical particles diameter of (0.42, 0.51, 0.61 and 0.79 cm, with $d_{p_{eff}}=0.55$ cm), bed porosity of 0.3711, packing height of 15.15 cm, bed diameter of 7.62cm [90] (Table 4.10)

a- ΔP vs u

b- f vs Re_p

Figure 5.14 a-pressure drop vs. velocity, b- Friction factor vs. Reynolds numbers for spherical particles diameter of (0.42, 0.51, 0.61 and 1.01cm ,with $d_{p_{eff}}=0.5738$ cm),bed porosity of 0.3719, packing height of 15.15 cm, bed diameter of 7.62 cm [90] (Appendix A.32)

Similar comparisons between experimental data and the achieved equation are shown in appendix A (A.32 to A.35).

The achieved equation show good results compared with the experimental data [90] as shown in figures 5.13 and 5.14. These results were better than the results from Ergun equation. These figures show clearly that the achieved equation results of pressure drop-velocity curves and the results of friction factor-Reynolds number curves are coincide with experimental results, while the results from Ergun equation lie above them. This is due to the differences in beds dimensions, packing shapes and sizes used by Ergun [7,111]. For example figures 5.13b and 5.14b which show that the values of friction factor of achieved equation results (range from 1.81-1.27 and 1.905-1.336 respectively) are coincide with experimental data results (range from 1.913-1.313 and 1.908-1.311 respectively), for Reynolds numbers (range from 267.8-2675 and 280.3-2799 respectively).

The achieved equation (3.9) was fitted for water flow through packed beds of quaternary sized spherical particles. In this fitting 5 sets of data [90] were used. In these sets 52 values of pressure drop versus velocity were taken. So, the singular form of the modified model for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 10.9685 \left(\frac{L}{d_p} \right)^{0.3339} \left(\frac{1}{\text{Re}} \right)^{0.1542} \varepsilon^{-3.9204} \phi^{0.1} \quad \dots (5.9)$$

The average percentage error was found to be 2.5303% between experimental work and the achieved equation.

The porosity used in the present model was evaluated from best fitting of experimental data of water flow through packed beds of quaternary-sizes spherical particles. This porosity is represented in the following equation.

$$\varepsilon = \frac{0.1397}{\left(0.4855 D_R^{3.9653} - 0.0533 d_p^{1.7936} \right)^{0.0869}} \quad \dots (5.10)$$

The above equation deviates from experimental with an average percentage error of $2.5 * 10^{-4} \%$.

5.4.1.6 Quinary sized spherical particles system

The values of pressure drop for water flow through packed beds of quinary sized spherical particles versus velocity were plotted in figure 5.15a. The values of friction factors versus Reynolds numbers were plotted in figure 5.15b.

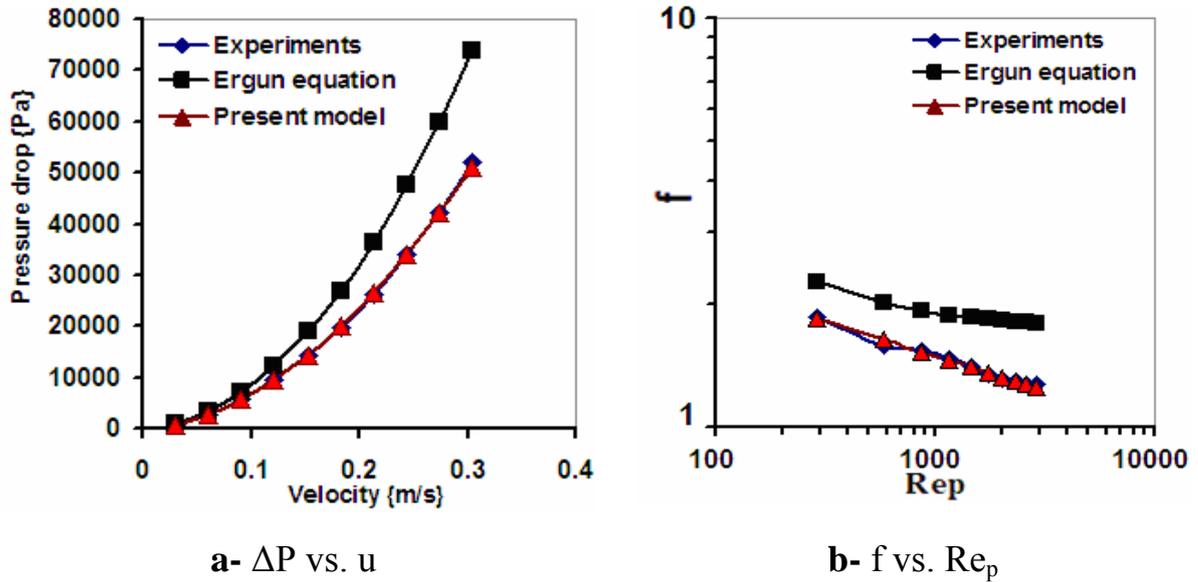

Figure 5.15 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for spherical particles diameter of (0.42, 0.51, 0.61, 0.79 and 1.01 cm, with $d_{p_{eff}}=0.61$ cm), bed porosity of 0.3623, packing height of 15.15cm, bed diameter of 7.62 cm [90] (Table 4.11)

From the above figure, it can be noticed that the achieved equation shows very good fitting to the experiment rather than Ergun equation, this appears in figure 5.15. Figure 5.15a shows that the model results of pressure drop-velocity curve lies on the experimental results curve. The values of pressure drop of figure 5.15a (range from 756.5 to 51176) are close to those of experimental data results (range from 767 to 52050), for velocity (range from 0.0305 to 0.3046). The same is seen in figure 5.15b which shows that the model results of friction factor-Reynolds number curve lies on the experimental results. The values of friction factor of figure 5.15b (range from 1.842 to 1.2567) are close to those of experimental data results (range from 1.868 to 1.271), for Reynolds numbers

(range from 290.4 to 2900). This means that the achieved equation is very close to the experimental results.

The achieved equation (3.9) was fitted for water flow through packed beds of quinary sized spherical particles. In this fitting one set of data [90] was used, which included 10 values of pressure drop versus velocity. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 1.6327 \left(\frac{L}{d_p} \right)^{1.8577} \left(\frac{1}{\text{Re}} \right)^{0.1687} \varepsilon^{-0.59} \phi^{0.7196} \quad \dots (5.11)$$

The average percentage errors were found to be 0.00262% between experimental work and the achieved equation.

The porosity used in the present model was proposed from best fitting of experimental data of water flow through packed beds of quinary sized spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{0.4592}{\left(1.1199 D_R^{0.5048} - 0.0706 d_p^{0.0147} \right)^{-0.2369}} \quad \dots (5.12)$$

The above correlation deviates from experimental data with an average percentage error of 0.10494 %.

5.4.2 General equation results

The results of the general equation are presented in this section. This presentation takes into account a comparison with Ergun equation and experimental data. The results of the general equation include mono spherical particles, mono non spherical particles, binary spherical particles, ternary spherical particles, quaternary spherical particles and quinary spherical particles systems.

The achieved equation (3.9) was fitted for water flow through packed beds of multi sized particles. In this fitting 115 sets of data from literatures [1, 3, 9, 20, 28, 54, 60, 84, 85, 86, 87, 88, 89, 90, 91, 93, 94, 96, 97, 98, 99, 100, 101,

102, 103, 104, 105, 106, 107] were used, which includes 1208 values of pressure drop versus velocity. So, the general form of the achieved equation for water flow through packed beds will be as follows:

$$\frac{\Delta P}{\rho u^2} = 55.3456 \left(\frac{L}{d_p} \right)^{1.2439} \left(\frac{1}{\text{Re}} \right)^{0.3316} \varepsilon^{-0.3947} \phi^{0.1} \quad \dots (5.13)$$

The average percentage errors were found to be 8.9981% between experimental work and the achieved equation.

The porosity used in the presented model was evaluated from best fitting of experimental data of water flow through packed beds of multi-sizes spherical particles. Which is as follows:

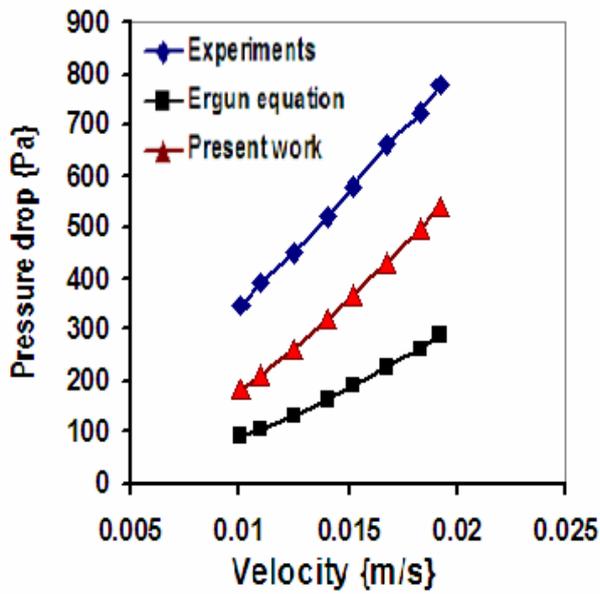

$$\varepsilon = \frac{0.148}{\left(1.6178 D_R^{6.3578} - 0.00028 d_p^{1.7666} \right)^{0.0579}} \quad \dots (5.14)$$

The above correlation deviates from experimental data with an average percentage error of 0.00082 %.

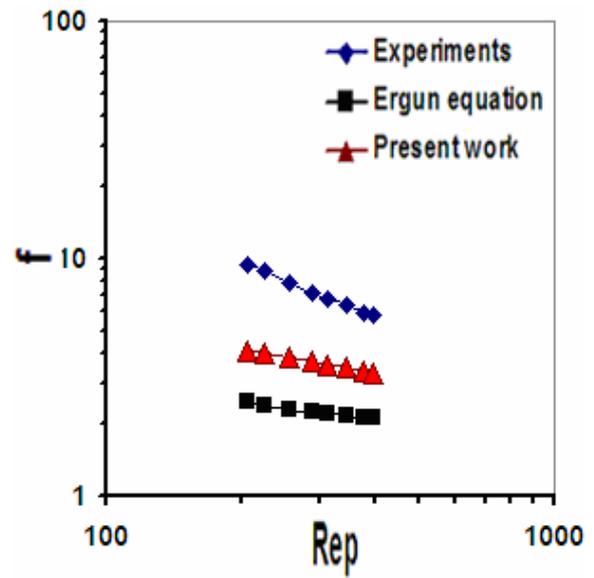

Equation 5.13 and 5.14 shown above can be used for all types of packing systems.

The values of pressure drop versus velocity for water flow through packed beds were plotted in Figs. 5.16a and 5.17a for mono spherical particles, Fig. 5.18a for mono non spherical particles, Figs. 5.19a and 5.20a for binary spherical particles, Figs. 5.21a and 5.22a for ternary spherical particles, Fig. 5.23a for quaternary spherical particles and Fig. 5.24a quinary spherical particles systems.

The values of friction factors versus Reynolds numbers were plotted in Figs. 5.16b and 5.17b for mono spherical particles, Fig. 5.18b for mono non spherical particles, Figs. 5.19b and 5.20b for binary spherical particles, Figs. 5.21b and 5.22b for ternary spherical particles, Fig. 5.23b for quaternary spherical particles and Fig. 5.24b quinary spherical particles systems.

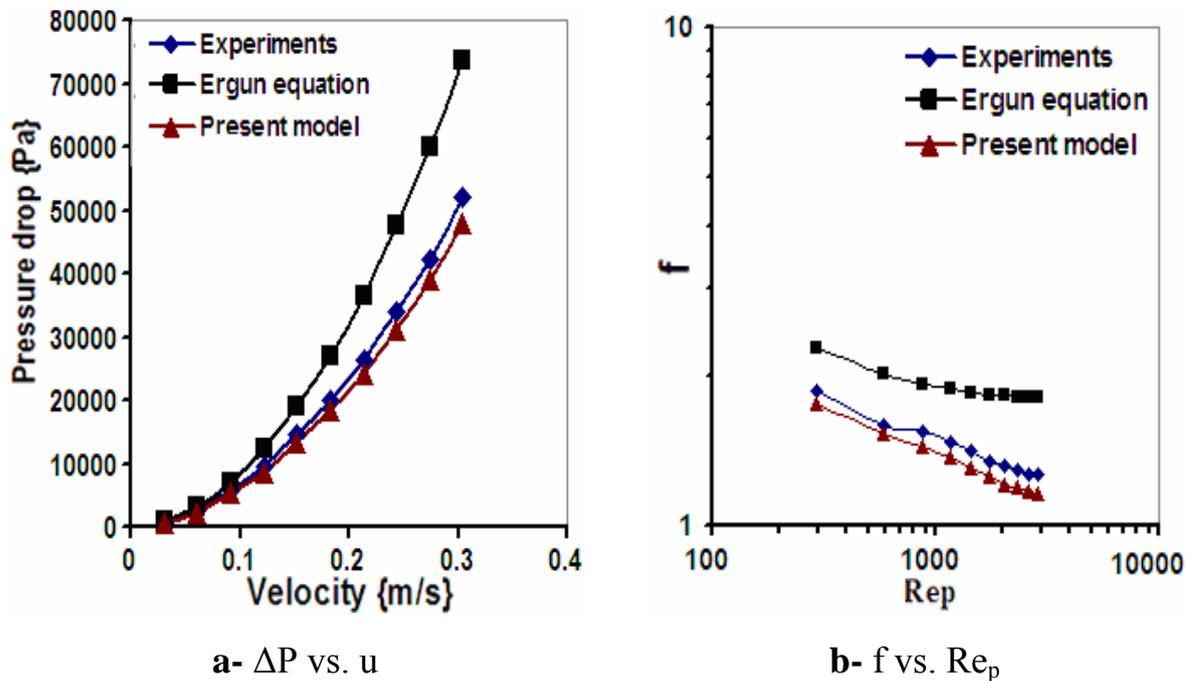

Figure 5.24 a-Pressure drops vs. velocity, b- Friction factor vs.Reynolds number for spherical particles diameter of (0.42, 0.51, 0.61, 0.79 and 1.01 cm, with $d_{p,eff}=0.61$ cm), bed porosity of 0.3623, packing height of 15.15 cm, bed diameter of 7.62 cm [90](Table 4.17)

It could be noticed from figures (5.16 to 5.24) that the achieved equation gave a good fitting to the experimental results which is better than Ergun equation. This is due to the fact that Ergun equation assumed smooth geometric surface area of the particles, but the irregular of the surface of the particles area would increase the drag force of the fluid moving past the particles (frictions) as well as the pressure drop [107,95]. So there is a certain deviation between Ergun results and experimental results. This deviation was also found between the achieved equation results and the Ergun equation.

The general equation can be used for any system of packing, while the singular equation for only one types of packing which was written for it ,and can not be used for another type. Figures (5.16 to 5.24) show the results of the

general equation for multi sized particles (equation 5.13), which can be compared with the results of singular equation for different types of packing system shown in figures (5.1, 5.2, 5.5, 5.8, 5.9, 5.10, 5.11, 5.13, 5.15 respectively). The comparisons between general and singular equations results show quite good agreement.

Figures 5.24b and 5.25b, shows that the values of friction of figure 5.24b (rang from 1.288 to 0.597) approximately the same values of figure 5.25b (range from 1.295 to 0.605); this is because they have approximately the same values of bed porosities and mean particles diameter.

It is clear that as the porosity decreases the friction factor decreases [92], in spite of pressure drop increases, and this is because that the friction factor is proportional to power three with porosity, while it is proportional to power one with pressure drop (equation 2.39).

5.5 Comparisons between achieved equation, Ergun equation and experimental results for air flow through packed bed

5.5.1 Singular equations results for different types of packing

5.5.1.1 Mono size spherical particle system

The values of pressure drop for air flow through packed beds of mono size spherical particles versus velocity were plotted in figures 5.25a, 5.26a and 5.27a. The values of friction factors versus Reynolds numbers were plotted in figures 5.25b, 5.26b and 5.27b.

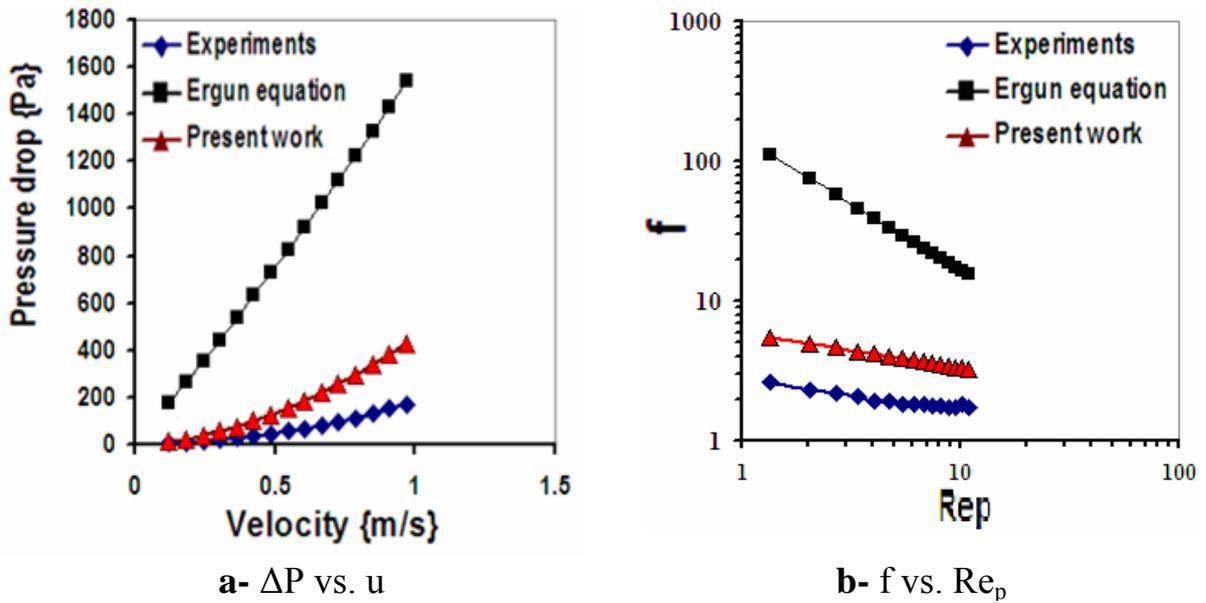

Figure 5.25 a- Pressure drop vs. velocity, b- Friction factor vs. Reynolds numbers for glass spheres of particle diameter 0.9987cm, bed porosity of 0.4181, packing height of 15.15cm, bed diameter of 7.64cm [89](Table 4.18)

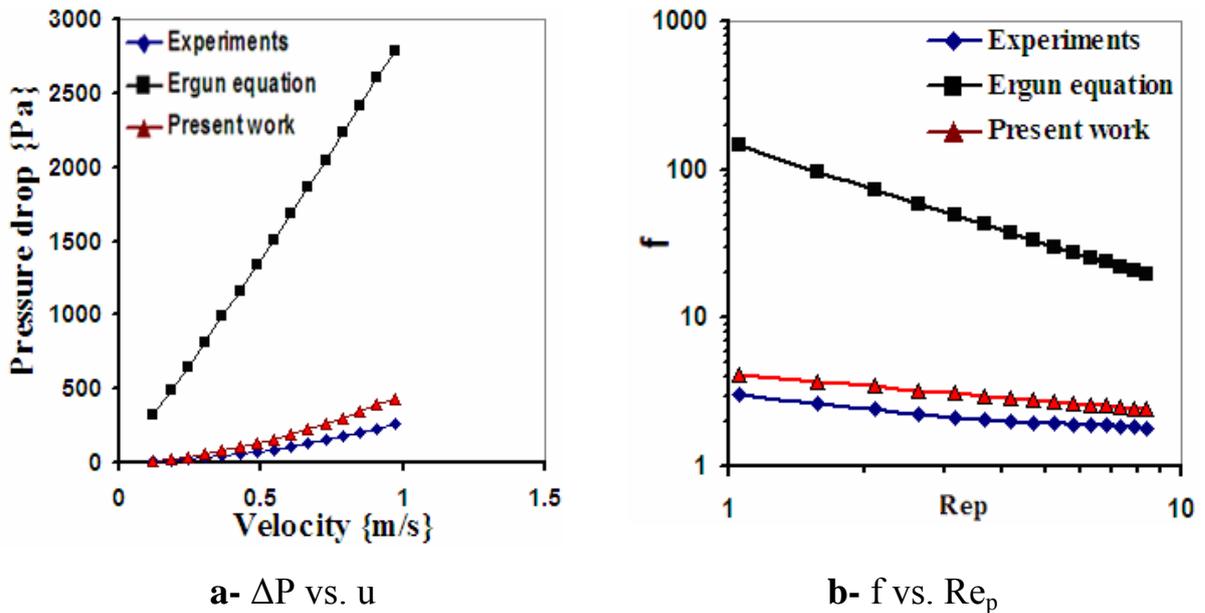

Figure 5.26 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particle diameter 0.7955 cm, bed porosity of 0.4088, packing height of 15.15 cm, bed diameter of 7.64 cm [89] (Appendix B.1)

Similar comparisons between experimental data and the achieved equation are shown in appendix B (B.2, B.3 and B.4).

Figures 5.25 and 5.26 shows that the achieved equation results show good agreement to the experimental results rather than Ergun equation results. Figure 5.26b shows that the achieved equation results of friction factor-Reynolds number curve is close to the values of friction factor-Reynolds number curve of the experimental results. The values of friction factor of achieved equation results of figure 5.26b (range from 4.1295 to 2.4259) are close to those of experimental data results (range from 3.0234 to 1.8114), for Reynolds numbers (range from 1.0502 to 8.4079). This means that the achieved equation results are very close to the experimental results.

The achieved equation (3.9) was fitted for air flow through packed beds of mono-sizes spherical particles. In this fitting 20 sets of data from literatures [89, 91, 96] were used, which include 336 values of pressure drop versus velocity. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 783.6491 \left(\frac{L}{d_p} \right)^{0.1937} \left(\frac{1}{\text{Re}} \right)^{0.2557} \varepsilon^{-0.3318} \phi \quad \dots (5.15)$$

The average percentage error was found to be 2.0224% between experimental work and the achieved equation.

The porosity used in the present model was evaluated from best fitting of experimental data of the air flow through packed beds of mono-sizes spherical particles. This porosity can be represented in the following equation.

$$\varepsilon = \frac{0.1202}{\left(0.1106 D_R^{-0.3381} - 2.4099 d_p^{0.9253} \right)^{0.8488}} \quad \dots (5.16)$$

The above correlation deviate's from experimental with an average percentage error of 0.00013%.

The wall affects bed porosity and increases its value. This appears in figure 5.25 where the bed porosity increases to a value of 0.4181, this wall effect may be due to the ratio of bed diameter (7.64cm) to the particles diameter

(0.9987cm) which is less than the supposed ratio (column diameter to the particle diameter should be greater than 10:1 [30,105])

Examining figures 5.25 and 5.26 give that the values of friction factor decrease sharply with increasing Reynolds numbers, because the fluid flow is at the laminar region (where the friction factor-Reynolds number curve is of slope of -1 and the friction factor-Reynolds number curve become straighter)[7].

In the following figures a comparisons between the present model and the experimental data are presented. The experimental data includes 10 sets of data [90], these sets include 217value of pressure drop versus velocity. This comparison is not included in the fitting of the present model and it has been made to check that equation 5.15 could be used for different conditions. Figure 5.27 is represented below for these calculations, while other tables of comparisons are presented in appendix B (B.6 and B.7)

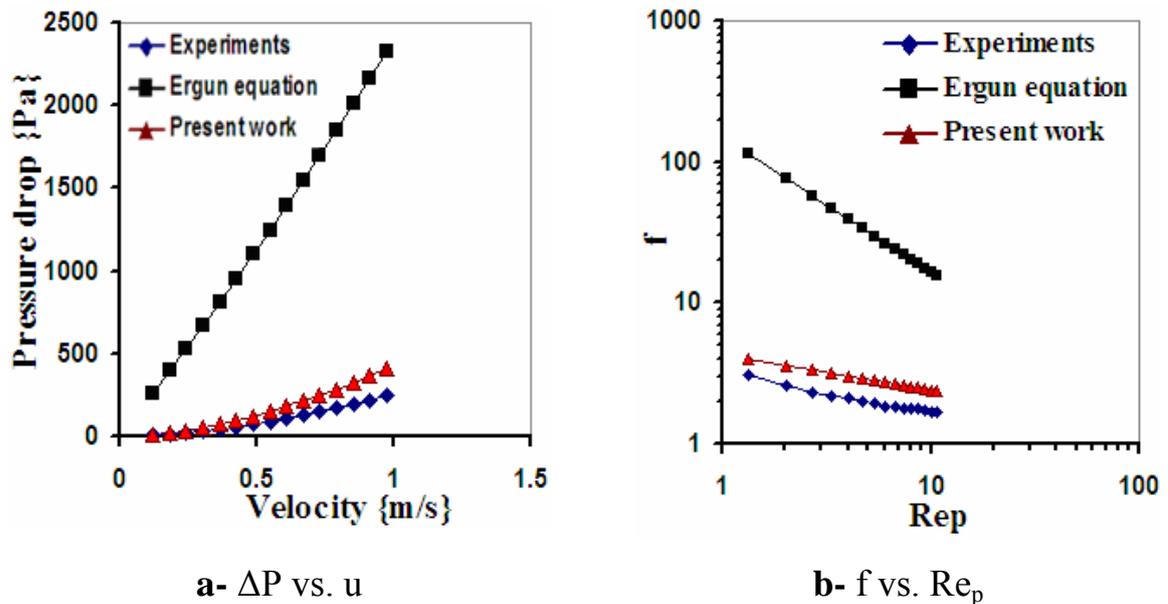

Figure 5.27 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particle diameter 1.01cm ,bed porosity of 0.4186 packing height of 20cm ,bed diameter of 7.62cm [90]. (Appendix B.5)

Although these figures are not included in the modeling they show very good agreement with experimental data.

5.5.1.2 Binary sized spherical particles system

The values of pressure drop for air flow through packed beds of binary sized spherical particles were plotted versus velocity in figures 5.28a, 5.29a and 5.30a. The values of friction factors versus Reynolds numbers were plotted in figures 5.28b, 5.29b and 5.30b.

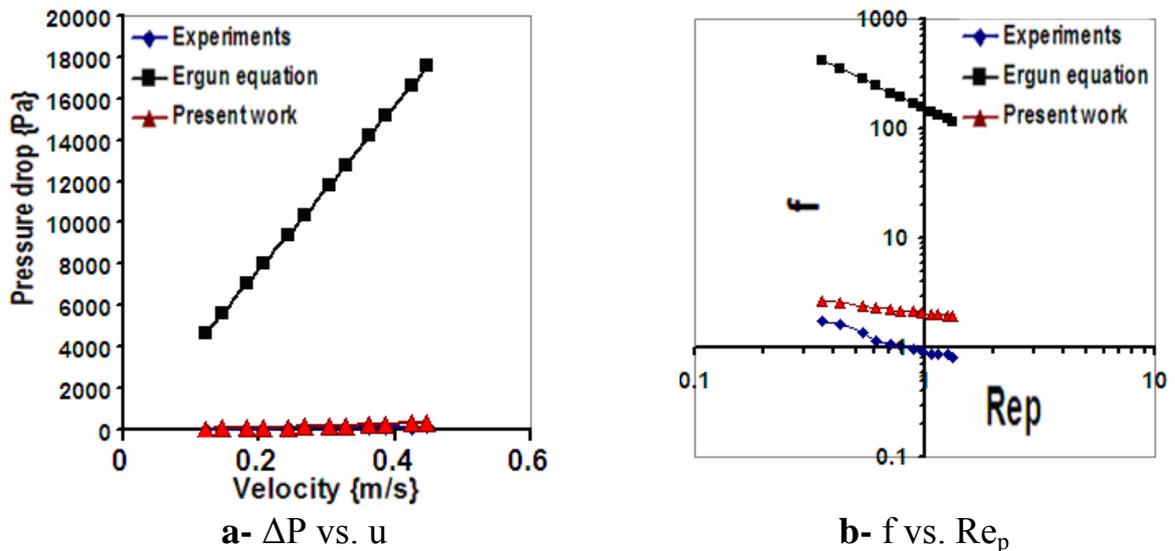

Figure 5.28 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter ($dp_1=0.24$ and $dp_2=0.42$, with $dp_{eff}=0.3055$ cm), bed porosity of 0.3515, packing height of 15.15 cm, bed diameter of 7.64cm [91] (Table 4.19)

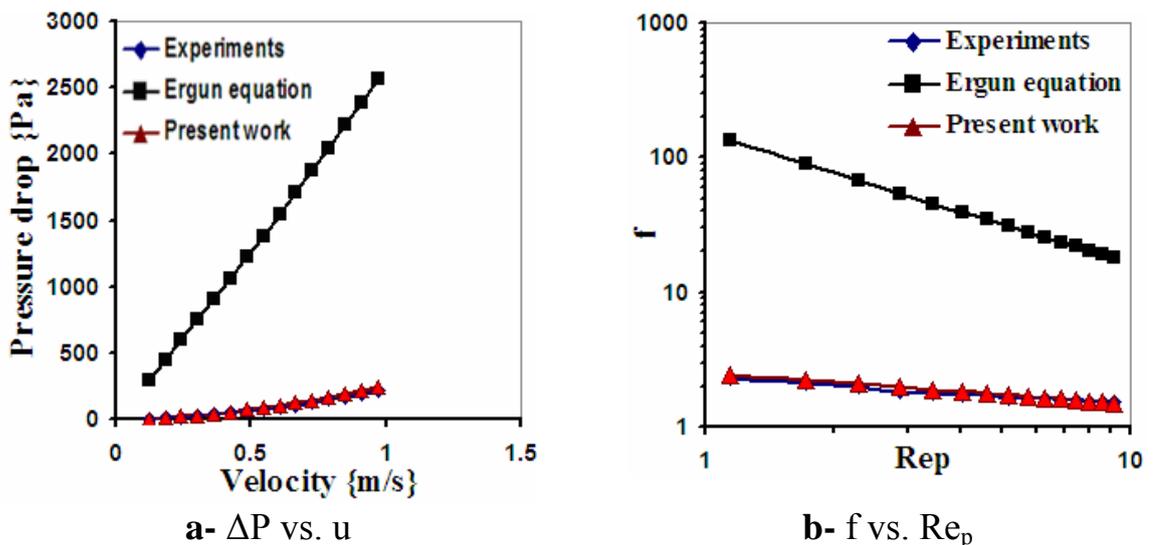

Figure 5.29 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particle diameters ($dp_1=0.9987$ and $dp_2=0.7955$ cm, with $dp_{eff}=0.886$ cm), bed porosity is 0.4079, bed diameter is 7.64cm, packing height is 15.15 cm [89] (Appendix B.8)

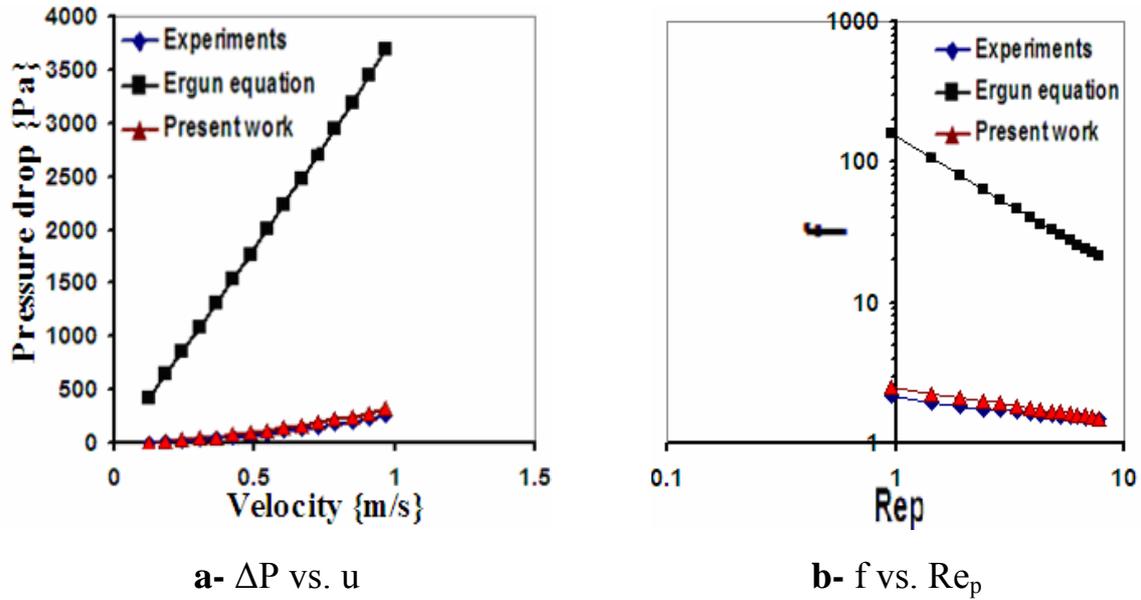

Figure 5.30 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particle diameters($dp_1=0.9987$ and $dp_2=0.6015$ cm, with $dp_{eff}=0.7508$ cm), bed porosity is 0.3986, bed diameter is 7.64 cm, packing height is 15.15 cm[89] (Appendix B.9)

Similar comparisons between experimental data and the achieved equation are shown in appendix B (B.10 to B.16).

The above figures show that, the achieved equation results satisfied the experiment results rather than Ergun equation, and this can be noticed from figure 5.28, 5.29 and 5.30, in these figures the pressure drop curves of the achieved equation results lies on the curves of the experimental results from literature [89, 90, 91, 96, 102].

The achieved equation (3.9) was fitted for air flow through packed beds of binary sized spherical particles. In this fitting 30 sets of data [89, 90, 91, 96,102] were used, which includes 391 values of pressure drop versus velocity were taken. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 3.2151 \left(\frac{L}{d_p} \right)^{1.105} \left(\frac{1}{\text{Re}} \right)^{0.2356} \varepsilon^{-1.6698} \phi \quad \dots (5.17)$$

The average percentage error was found to be 3.13327% between experimental work and the achieved equation.

The porosity used in the present model was correlated using the best fitting of experimental data of air flow through packed beds of binary-sized spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{0.1611}{\left(1.6782 D_R^{-0.0469} - 1.9749 d_p^{0.0191} \right)^{0.3762}} \quad \dots (5.18)$$

The above correlation deviates from experimental with an average percentage error of $0.991 \times 10^{-3} \%$. This means that they are identical.

It can be noticed that the values of friction factor of binary sizes system are less than those of mono sizes system for approximately near values of bed porosity. For example, Fig. 5.29 (binary system) shows that the values of friction factor range from 2.4479 to 1.4997 are less than those of Fig. 5.25 (mono system) which range from 5.5328 to 3.2503, This is because the contacting surface area of binary size system (677.2009 m^{-1}) is greater than that of mono size system (600.7810 m^{-1}).

As the velocity of fluid increases the pressure drop across the bed increases, e.g., table 4.19 shows that the pressure drop values increase from 33.074 to 333.084 Pa with increasing the fluid velocity from 0.121 to 0.448 m/s.

5.5.1.3 Ternary sized spherical particles system

The values of pressure drop for air flow through packed beds of ternary sized spherical particles versus velocity were plotted in figures 5.31a, 5.32a and 5.33a. The values of friction factors are plotted versus Reynolds numbers in figures 5.31b, 5.32b and 5.33b.

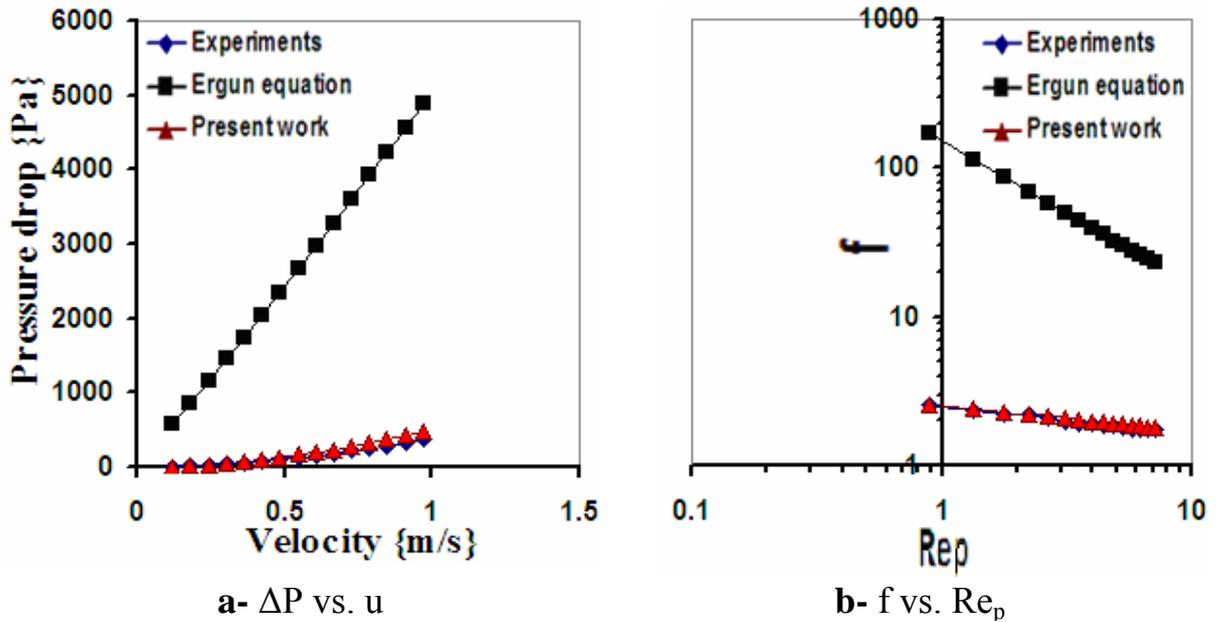

Figure 5.31 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particle diameters of (0.9987, 0.7955 and 0.509 cm, with $d_{p_{eff}}=0.7104$ cm), bed porosity of 0.3796, packing height of 15.15 cm, bed diameter of 7.64 cm [89] (Table 4.20)

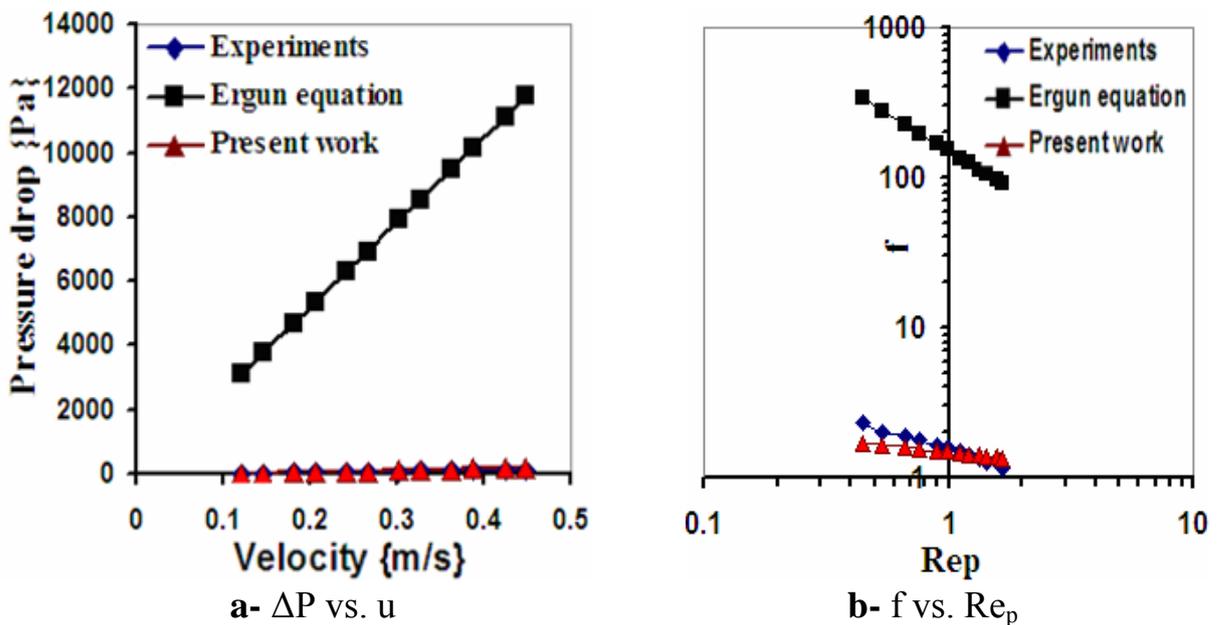

Figure 5.32 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particle diameters (0.24, 0.42 and 0.82 cm, with $d_{p_{eff}}=0.3862$ cm), bed porosity of 0.3428, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Appendix B.17)

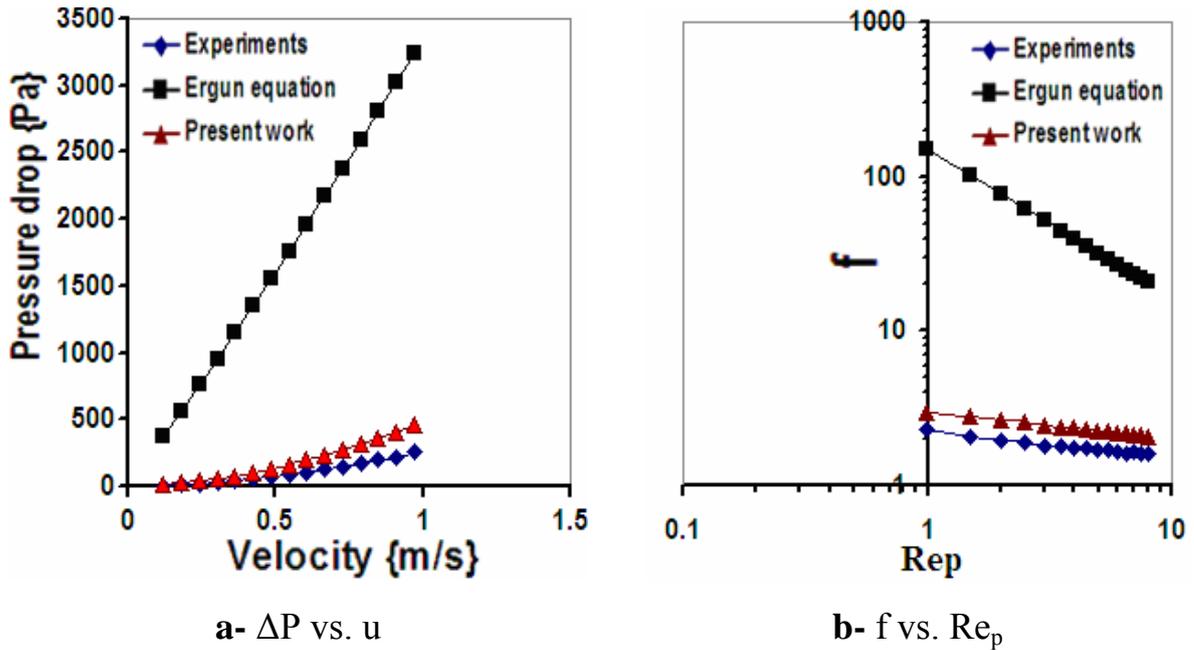

Figure 5.33 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass of particles diameter (0.9987, 0.7955 and 0.6015 cm, with $d_{p_{eff}}=0.7651$ cm), bed porosity of 0.3899, packing height of 15.15cm, bed diameter of 7.64 cm [89] (Appendix B.18)

Similar comparisons between experimental data and the modified model are shown in appendix B (B.19 to B.25))

It can be noticed from figures 5.31, 5.32 and 5.33 that the achieved equation results gave a good fitting to the experiment rather than Ergun equation. This is due to the fact that Ergun derived the values for the constants through experiments where the packing was small, non-spherical, and rough [2].

The bed porosity highly affects the pressure drop and inversely proportional to it, this is because that when the porosity increases the resistance to fluid flow through the bed decreases. For example in figure 5.31a for bed porosity of 0.3796 the pressure drop values which range from 10.62 to 472.2 Pa are greater than those of figure 5.33a, while for larger

values of bed porosity of 0.3899 the pressure drop values range from 10.36 to 460.6 Pa, for the same value of (bed diameter 7.64cm, packing height 15.15cm, and near values of effective particle diameters ($d_{p_{eff}}$) of figure 5.31a (0.7104cm) close to the value of figure 5.33a (0.7615cm).

The achieved equation (3.9) was fitted for ternary sized spherical particles system using 30 sets of data from literature [98, 90, 91], which includes 340 values of pressure drop versus velocity. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 4.9298 \left(\frac{L}{d_p} \right)^{1.2343} \left(\frac{1}{Re} \right)^{0.1757} \varepsilon^{-0.9865} \phi \quad \dots (5.19)$$

The average percentage error was found to be 2.18193% between experimental work and the achieved equation.

The porosity used in the presented model was proposed from best fitting of experimental data of air flow through packed beds of ternary-sizes spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{0.1834}{\left(4.3115 D_R^{-0.0771} - 5.6073 d_P^{0.0167} \right)^{0.3228}} \quad \dots (5.20)$$

The above correlation deviates from experimental data with an average percentage error of 0.00054 %.

5.5.1.4 Quaternary sized spherical particles system

The values of pressure drop for air flow through packed beds of quaternary sized spherical particles versus velocity were plotted in figures 5.34a, 5.35a and 5.36a. The values of friction factors versus Reynolds numbers were plotted in figures 5.34b, 5.35b and 5.36b.

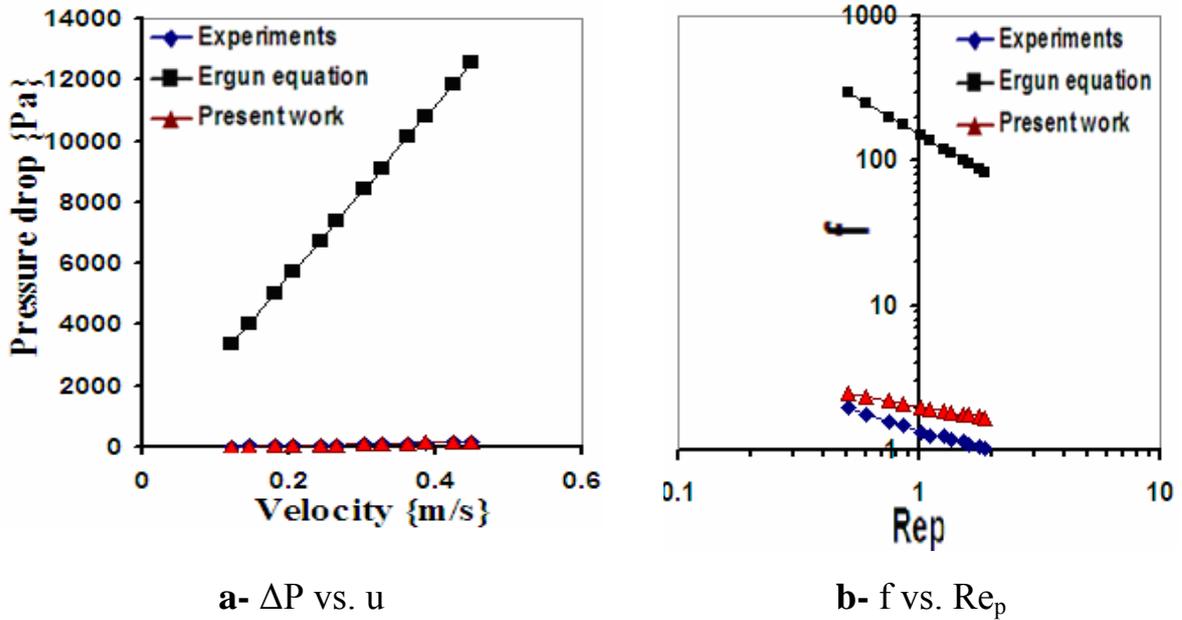

Figure 5.34 a-Pressure drop vs.velocity, b-Friction factor vs. Reynolds numbers. for glass spheres of particle diameters of (0.24, 0.42, 0.82 and 1.03 cm, with $d_{p,eff}=0.4578$ cm), bed porosity of 0.3532, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Table 4.21)

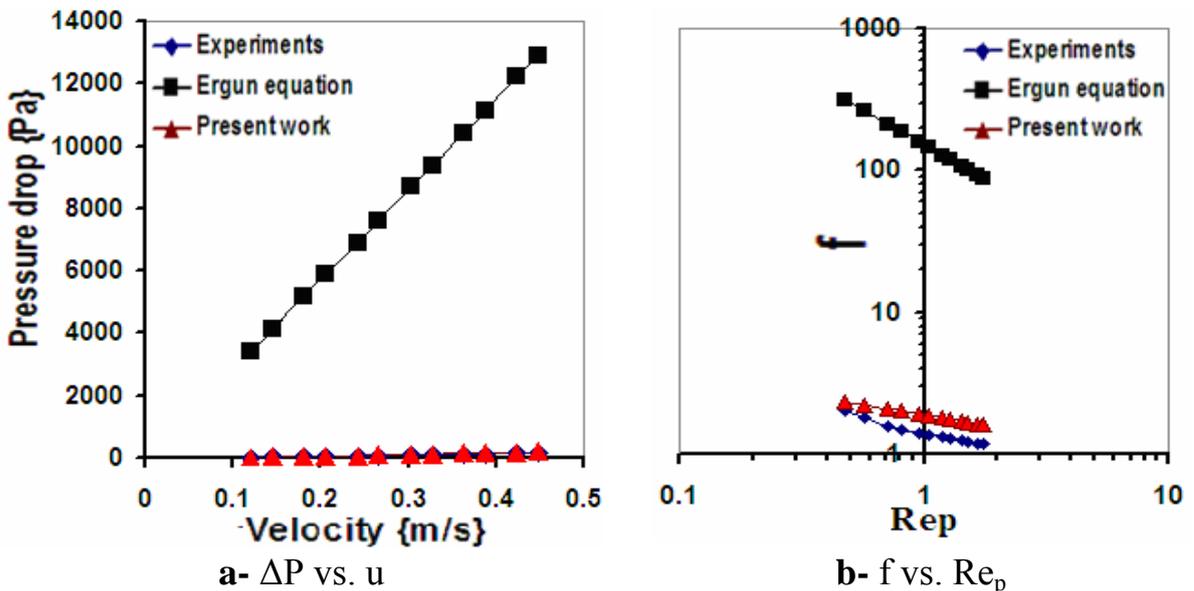

Figure 5.35 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass of particles diameter (0.24, 0.42, 0.82 and 0.61 cm, with $d_{p,eff}=0.4252$ cm), bed porosity of 0.3474, packing height of 15.15 cm, bed diameter of 7.64cm[91] (Appendix B.26)

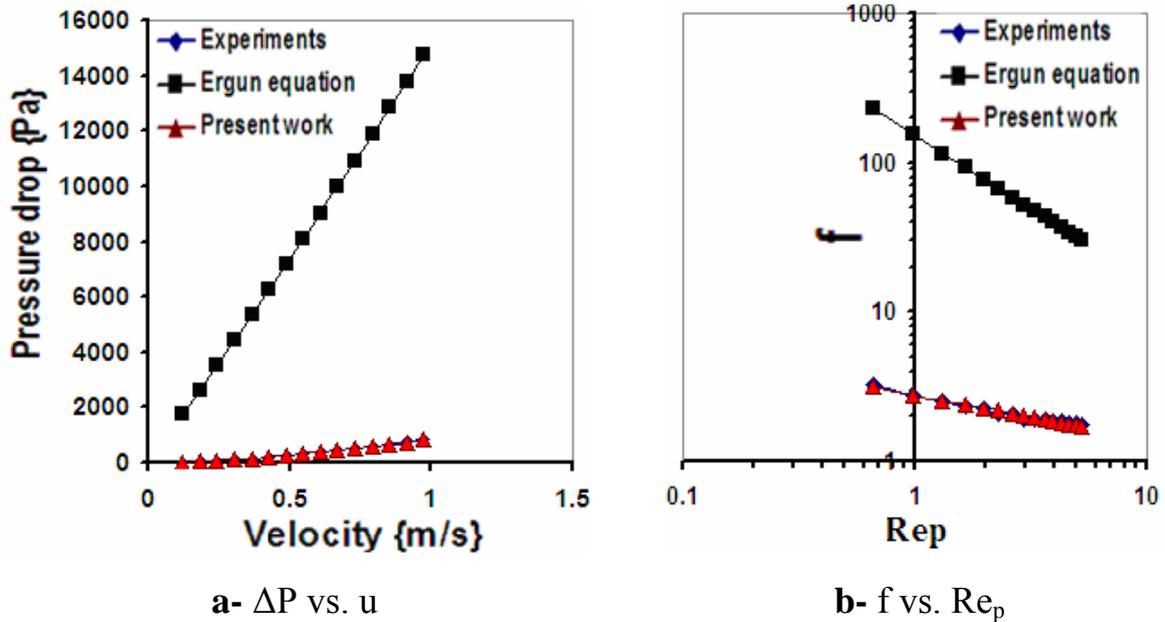

Figure 5.36 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter (0.42, 0.51, 0.61 and 0.79 cm, with $d_{p,eff}=0.552$ cm), bed porosity of 0.371, packing height of 20 cm, bed diameter of 7.62 cm [90] (Appendix B.27)

Similar comparisons between experimental data and the achieved equation are shown in appendix B (B.28 to B.32).

From the above figures, one can recognize that the achieved equation gave a good fitting to the experiment rather than Ergun equation; this difference may lie on the basic concepts of Ergun equation itself [6, 77]. For example in figure 5.36a the values of pressure drop of experiment results were approximately close to the values of pressure drop of model results range from (14.144 - 537.62 and 14.3906 - 498.884)Pa, since they have the same values of velocity (range from 0.1218 - 0.9746) m/s . The same thing for figure 5.36b the values of friction factor of experiment results were approximately close the values of friction factor of the model results range from (3.4419 - 2.1802 and 4.3011 - 2.3289) since they have the same values of Reynolds numbers (range from 1.0457 - 8.3673).

The values of friction factor of figures 5.34b and 5.35b were approximately close to each other (range from 2.4536-1.6676 and 2.3595-1.6037) since they have close values of Reynolds numbers (range from 0.508-1.8688 and 0.4756-1.76101) and porosities (0.3532 and 0.3474) in spite of the different diameters of particles.

Equation (3.9) was fitted for air flow through packed beds of quaternary sized spherical particles, In this fitting 10 sets of data were used [90,91], which includes 136 values of pressure drop versus velocity. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 5.2649 \left(\frac{L}{d_p} \right)^{1.3899} \left(\frac{1}{\text{Re}} \right)^{0.295} \varepsilon^{-0.2323} \phi \quad \dots (5.21)$$

The average percentage error was found to be 2.49298% between experimental work and the achieved equation.

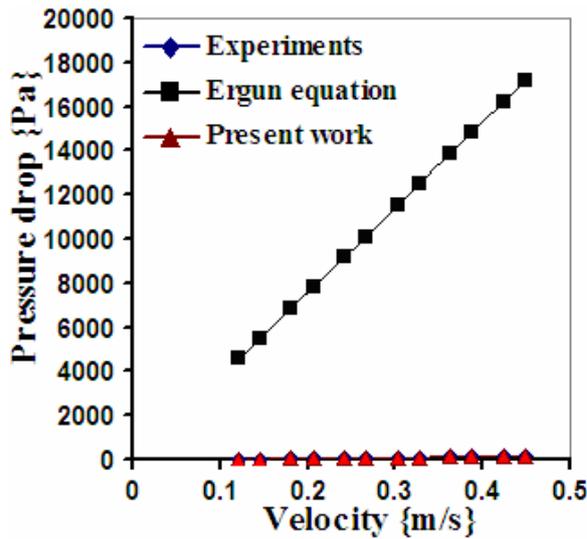

The porosity used in the present model was evaluated from best fitting of experimental data of air flow through packed beds of quaternary sized spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{1.4931}{(0.0946 D_R^{-0.6967} + 0.8098 d_p^{0.3707})^{-3.7901}} \quad \dots (5.22)$$

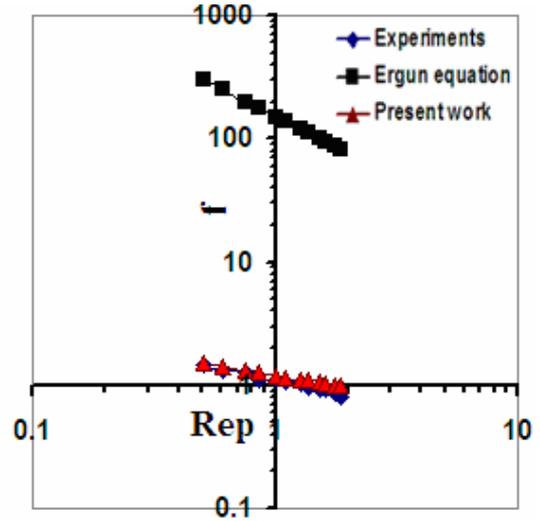

The above correlation deviates from experimental data with an average percentage error of 2.11835%.

5.5.1.5 Quinary sized spherical particles system

The values of pressure drop for air flow through packed beds of quinary sized spherical particles versus velocity were plotted in figures 5.37a and 5.38a. The values of friction factors versus Reynolds numbers were plotted in figures 5.37b and 5.38b.

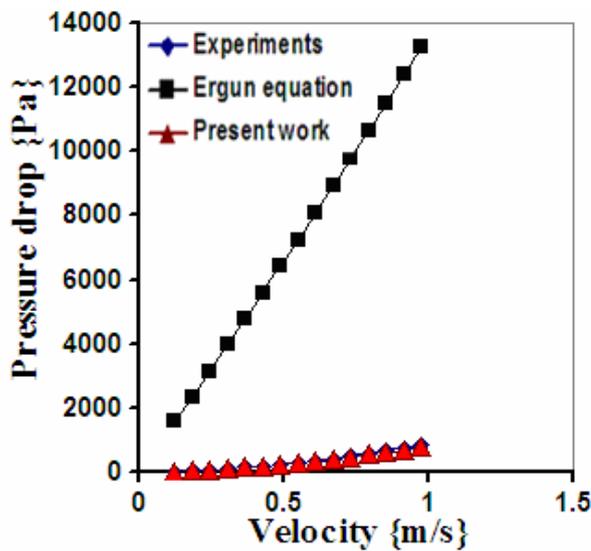

a- ΔP vs. u

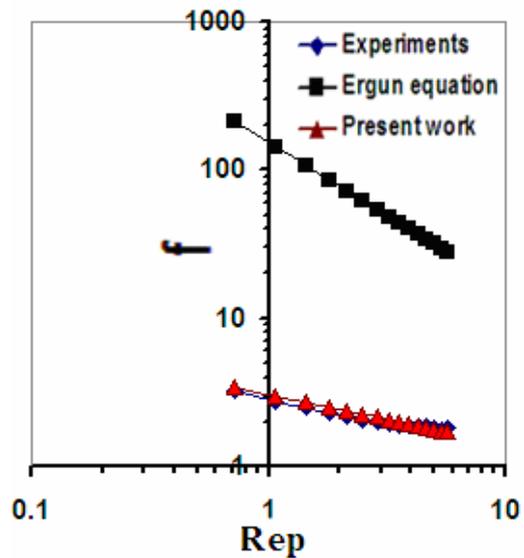

b- f vs. Re_p

Figure 5.37 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass sphere of particles diameter (0.24, 0.42, 0.82, 0.61 and 1.03 cm, with $d_{p,eff}=0.4818$ cm), bed porosity of 0.2977, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Table 4.22)

a- ΔP vs. u

b- f vs. Re_p

Figure 5.38 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass sphere of particles diameter (0.42, 0.51, 0.61, 0.79 and 1.01 cm, with $d_{p,eff}=0.607$ cm), bed porosity of 0.3694, packing height of 20 cm, bed diameter of 7.62 cm[90] (Appendix B.33)

It can be noticed from the above figures that the achieved equation gave very good fitting to the experiment rather than Ergun equation. The achieved equation results of friction factor-Reynolds number curves and pressure drop-velocity curves lie on the experimental results curves, while the results of Ergun lies above them; this is due to the differences in beds dimensions, packing shapes and sizes [105].

Figure 5.37b shows that the values of friction factor are less than the values of friction factor in all mixtures because minimum porosity value was achieved in this system. In this figure the value of friction factor range from 1.50822 to 0.97532 for a minimum porosity of 0.2977.

The achieved equation (3.9) was fitted for air flow through packed beds of quinary-sized spherical particles, in this fitting two sets of data were used [90,91], which includes 30 values of pressure drop versus velocity. So, the singular form of the achieved equation for this case will be as follows:

$$\frac{\Delta P}{\rho u^2} = 0.5597 \left(\frac{L}{d_p} \right)^{2.1127} \left(\frac{1}{\text{Re}} \right)^{0.3301} \varepsilon^{-0.1012} \phi \quad \dots (5.23)$$

The average percentage error found to be 0.6547% between experimental work and the achieved equation.

The porosity used in the present model was proposed from best fitting of experimental data of air flow through packed beds of quinary-sized spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{0.2279}{\left(0.5961 D_R^{0.3926} - 0.7136 d_p^{0.2336} \right)^{0.0603}} \quad \dots (5.24)$$

The above correlation deviates from experimental with an average percentage error of 0.00683 %.

5.5.2 General equation results

The following presentation of results and comparisons are based on general equation fittings for all systems considered in the present work. This system considered includes mono spherical particles, mono non spherical particles, binary spherical particles, ternary spherical particles, quaternary spherical particles and multi-sizes of spherical particles systems.

The achieved equation (3.9) was fitted for air flow through packed beds of multi-sized spherical particles. In this fitting 102 sets of data were used, which includes 1450 values of pressure drop versus velocity. So, the general form of the achieved equation for air flow through packed bed will be as follows:

$$\frac{\Delta P}{\rho u^2} = 14.1817 \left(\frac{L}{d_p} \right)^{0.7736} \left(\frac{1}{\text{Re}} \right)^{0.3419} \varepsilon^{-1.1315} \phi \quad \dots (5.25)$$

The average percentage error was found to be 7.05719% between the experimental work and the achieved equation.

The porosity used in the present model was evaluated from best fitting of experimental data of air flow through packed beds of multi-sized spherical particles. This porosity is represented in the following equation:

$$\varepsilon = \frac{1.0337}{\left(0.0014 D_R^{0.1418} + 1.8929 d_p^{1.161} \right)^{-0.197}} \quad \dots (5.26)$$

The above correlation deviates from experimental with an average percentage error of 0.0309 %.

Equation 5.25 and 5.26 can be used in all types of packing systems.

The values of pressure drop versus velocity for air flow through packed beds were plotted in Figs. 5.39a and 5.40a for mono spherical particles, Figs. 5.41a and 5.42a for binary spherical particles, Figs. 5.43a and 5.44a for ternary spherical particles, Fig. 5.45a and 5.46a for quaternary spherical particles, Fig. 5.47a and 5.48a for quinary spherical particles systems. The values of friction factors versus Reynolds numbers were plotted in Figs. 5.39b and 5.40b for mono spherical particles, Figs. 5.41b and 5.42b for binary spherical particles, Figs.

5.43b and 5.44b for ternary spherical particles, Fig. 5.45b and 5.46b for quaternary spherical particles, Fig. 5.47b and 5.48b for quinary spherical particles systems.

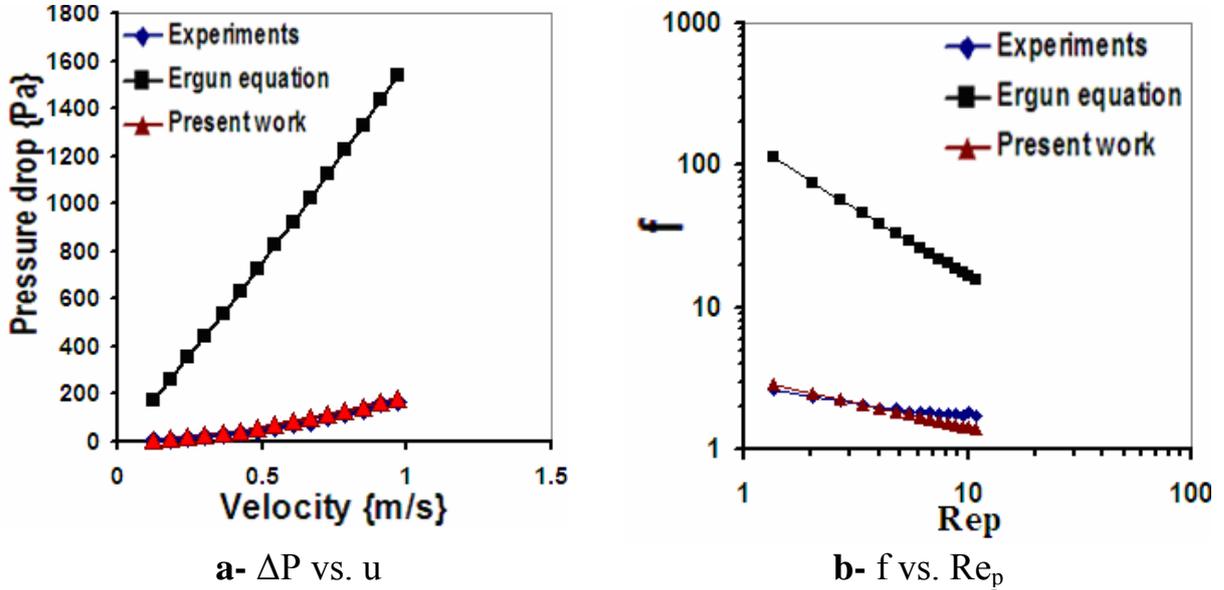

Figure 5.39 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass of particles diameter 0.9987 cm, bed porosity of 0.4169, packing height of 15.15 cm, bed diameter of 7.62 cm [89] (Table 4.23)

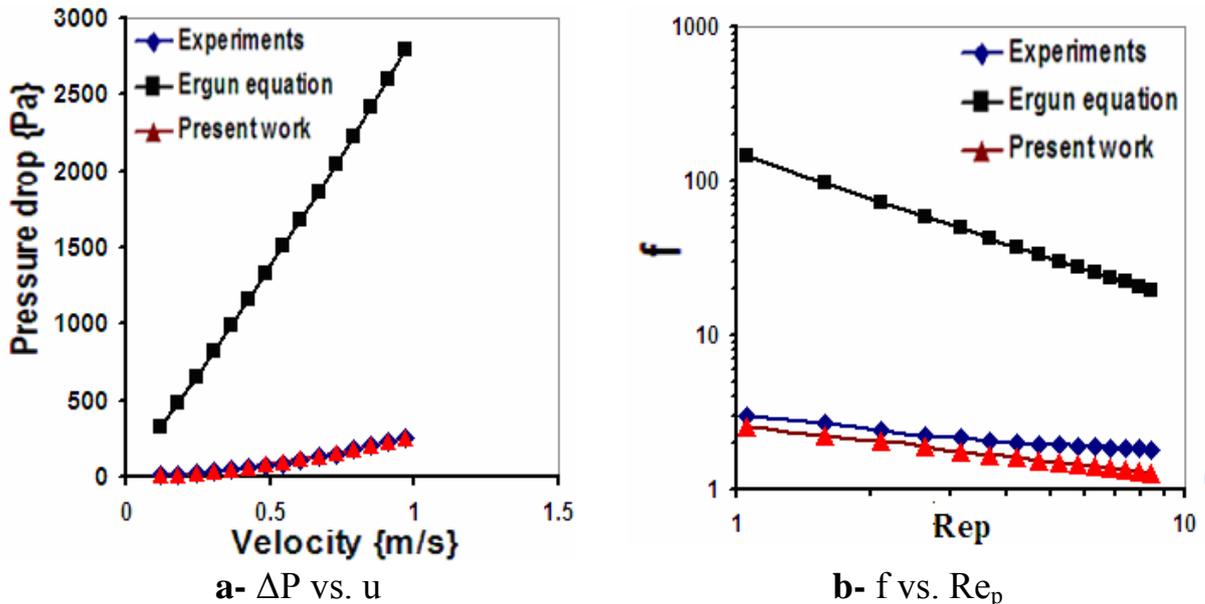

Figure 5.40 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass of particles diameter 0.7955 cm, bed porosity of 0.39804, packing height of 15.15 cm, bed diameter of 7.62 cm [89] (Appendix B.34)

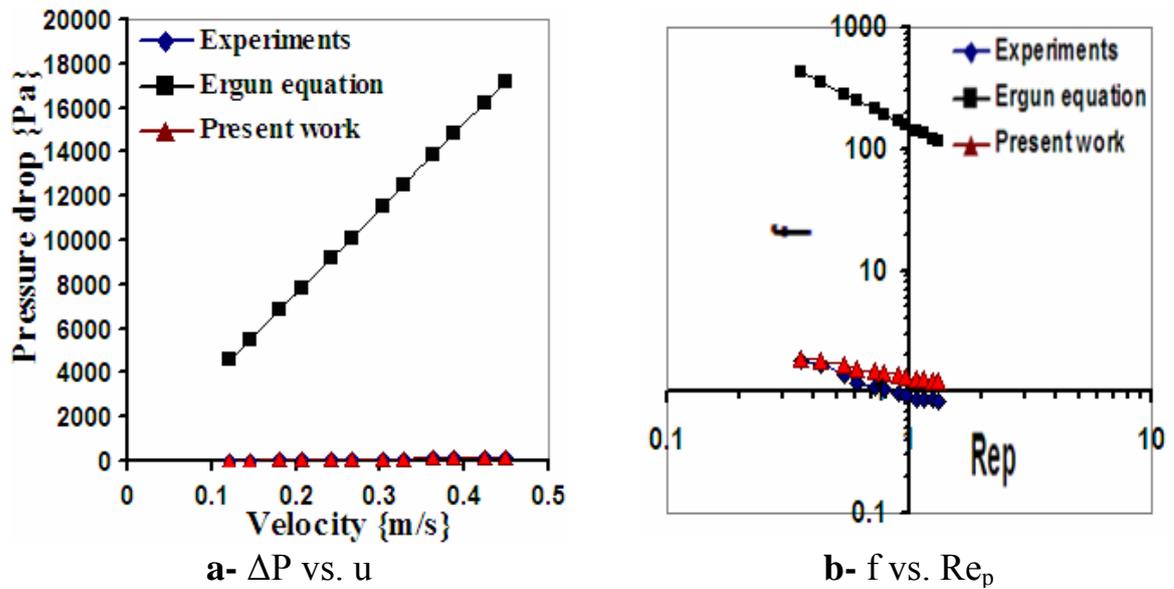

Figure 5.41 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameters ($dp_1=0.24$ and $dp_2=0.42$ cm, with $dp_{eff}=0.3055$ cm), bed porosity of 0.3343, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Table 4.24)

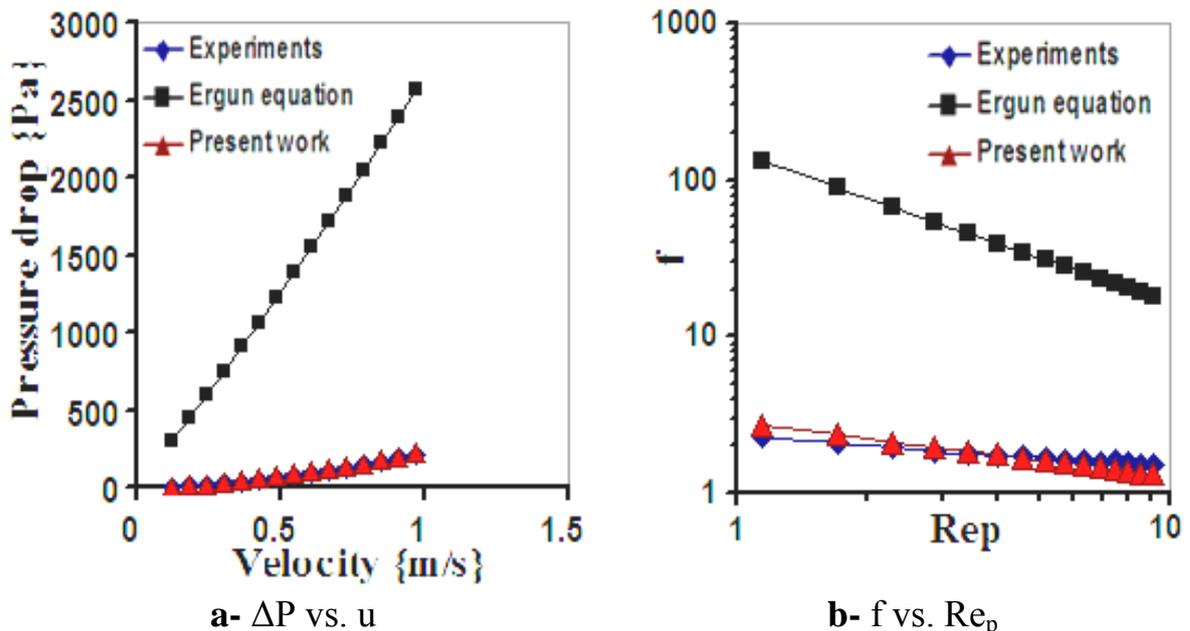

Figure 5.42 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter ($dp_1=0.9987$ and $dp_2=0.7955$ cm, with $dp_{eff}=0.886$ cm), bed porosity is 0.4068, bed diameter is 7.64 cm, packing height is 15.15 cm [89] (Appendix B.35)

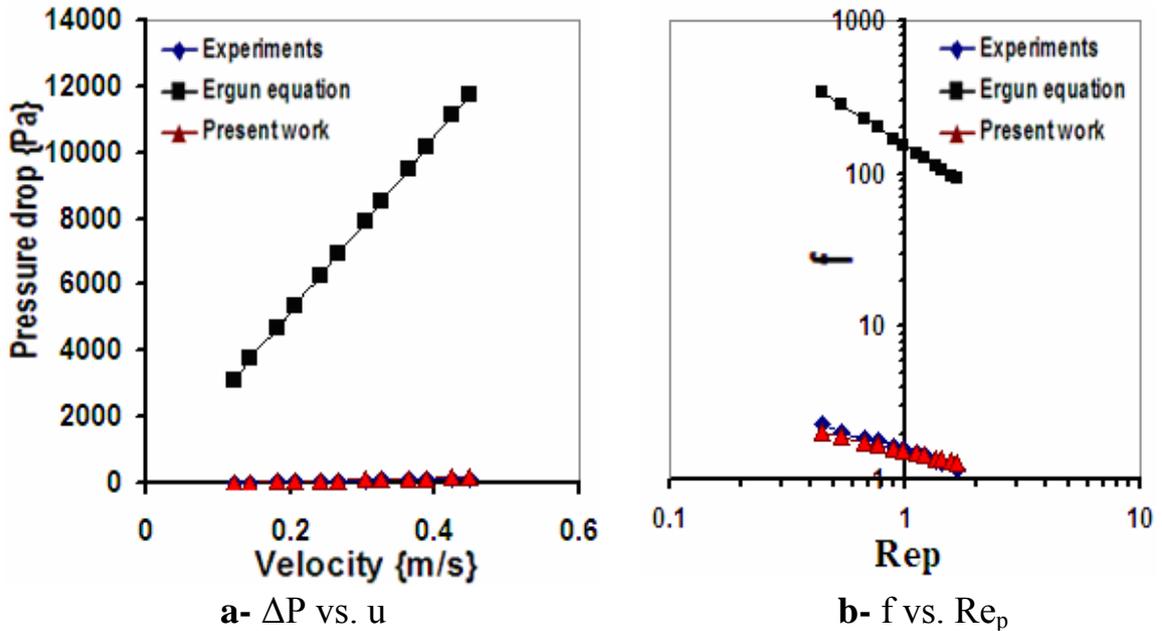

Figure 5.43 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameters (0.24, 0.42 and 0.82 cm, with $d_{p_{eff}}=0.3862$ cm), bed porosity of 0.3495, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Table 4.25)

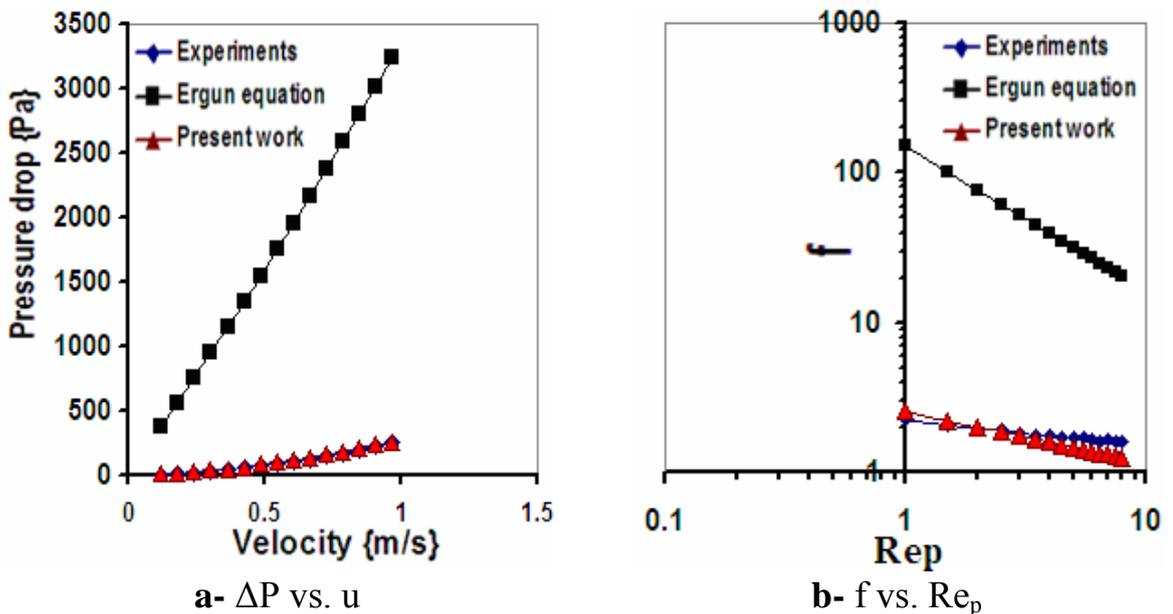

Figure 5.44 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter (0.9987, 0.7955 and 0.6015 cm, with $d_{p_{eff}}=0.7651$ cm), bed porosity of 0.3949, packing height of 15.15 cm, bed diameter of 7.64 cm [89] (Appendix B.36)

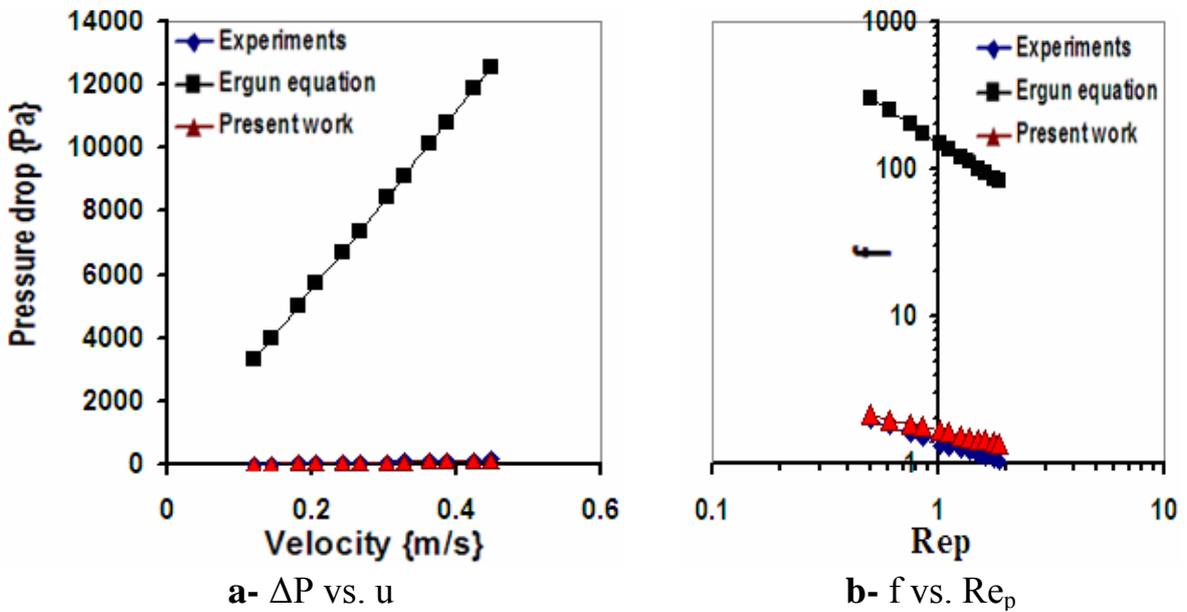

Figure 5.45 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter (0.24, 0.42, 0.82 and 1.03 cm, with $d_{p_{eff}}=0.4578$ cm), bed porosity of 0.3581, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Table 4.26)

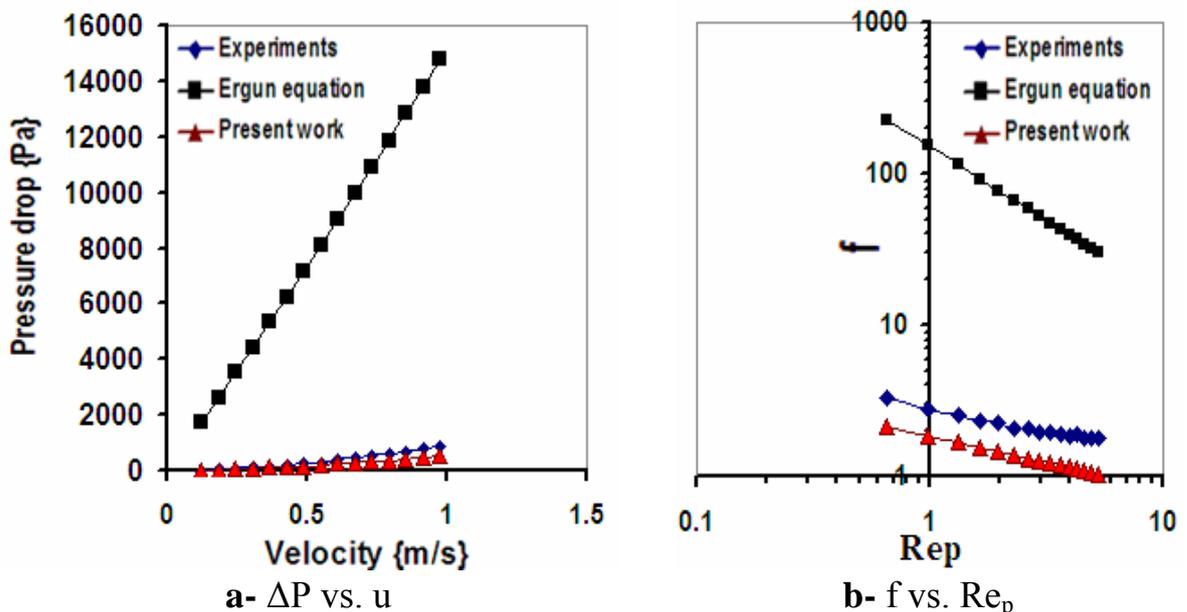

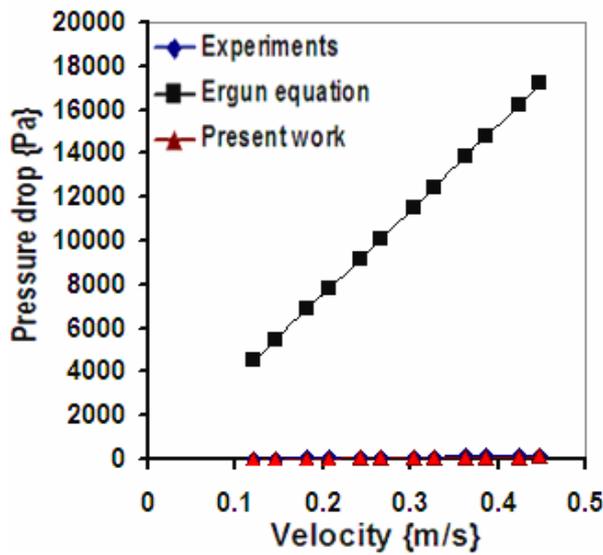

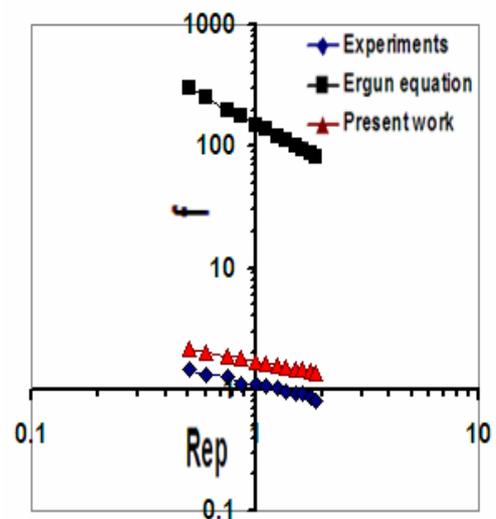

Figure 5.46 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter (0.42, 0.51, 0.61 and 0.79 cm, with $d_{p_{eff}}=0.552$ cm), bed porosity of 0.3707, packing height of 20 cm, bed diameter of 7.62 cm [90] (Appendix B.37)

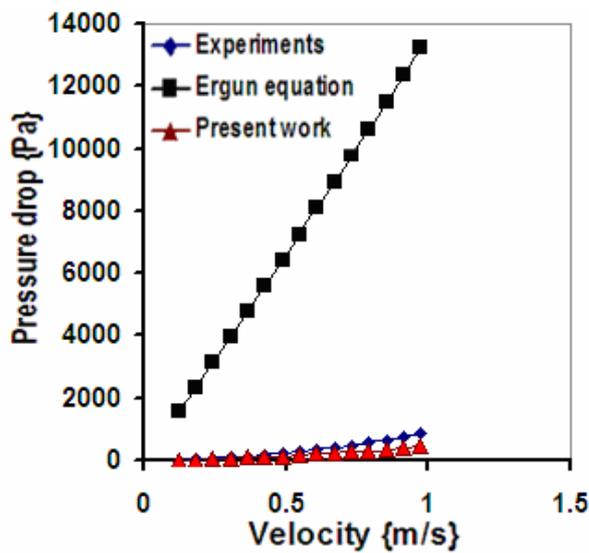

a- ΔP vs. u

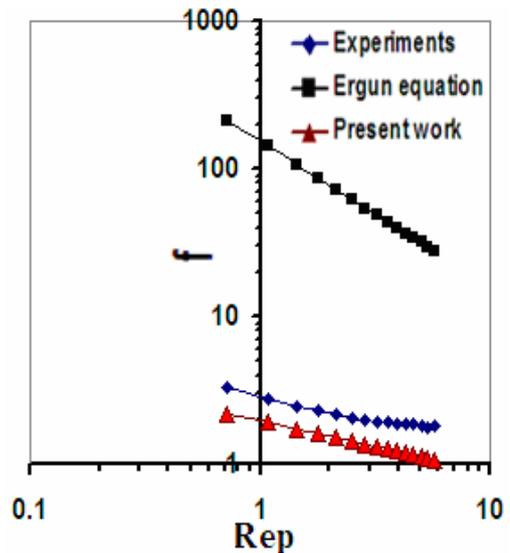

b- f vs. Re_p

Figure 5.47 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass of particles diameter (0.24, 0.42, 0.82, 0.61 and 1.03 cm, with $d_{p,eff}=0.4818$ cm), bed porosity of 0.3615, packing height of 15.15 cm, bed diameter of 7.64 cm [91] (Table 4.27)

a- ΔP vs. u

b- f vs. Re_p

Figure 5.48 a-Pressure drop vs. velocity, b-Friction factor vs. Reynolds numbers for glass spheres of particles diameter (0.42, 0.51, 0.61, 0.79 and 1.01 cm, with $d_{p,eff}=0.607$ cm), bed porosity of 0.3694, packing height of 20 cm, bed diameter of 7.62 cm [91] (Appendix B.38)

The general equation could be used for any packing system, while the singular equation for only one types of packing (which is written for it), and can not be used for another type. For example equation (5.15) can be used for mono spherical system only. This is true for all other equation (5.17, 5.19, 5.21 and 5.23). The same thing can be said for the porosity equations. Figures 5.39 to 5.48 show the results of the general equation for multi sized particles (equation 5.25), which can be compared with the results of singular equations for different types of packing system shown in figures 5.25, 5.26, 5.28, 5.29, 5.32, 5.43, 5.34, 5.36, 5.37 and 5.38 respectively.

It can be noticed from figures (5.39 to 5.48) that the achieved equation gave a good fitting to the experiment better than Ergun equation. The achieved equation results of pressure drop-velocity curves and friction factor-Reynolds number curves are close to the experimental results curves, while the results from Ergun equation were far from the experimental results; this may be due to:

1. The difference of bed dimensions (diameter and height of bed) [96].
2. The difference of void fraction (difference of packing shape and size) [101].
3. Ergun designed his equation using completely different procedures than experimental data work, so it was no surprise when its failure was confirmed. Ergun used pea gravel for the packed bed and air for the fluid; unlike experiments were glass is used for the packed bed and air for the fluid [84].
4. Other reasons of this large deviation from Ergun equation, that Ergun's equation does not take in to consideration wall effects, because Ergun considered that in to packed beds it is generally assumed that the diameter of the packing is close to that of the column; therefore, there are no wall effects [93].

Chapter Six

Conclusions and Recommendations for Future Work

6.1 Conclusions

1. The achieved equations had successfully described the effects of different parameters on pressure drop of fluid flow through packed beds, like fluid velocity, height of packing, type of packing particles, particles size, bed porosity and bed diameter, compared with the experimental results.
2. It was found that an increase in particle diameter causes a decrease in pressure drop, this is due to the fact that when the particle diameter increase's the specific surface area of it decreases, and this leads to a decrease in the resistance to fluid flow.
3. The particle size and size distribution highly affect the bed porosity. For mono size packing, the lower the particle size, the lower is the bed porosity. The porosity of multi- size systems are generally less than those of mono size systems, because the particles of smaller sizes tend to fill the void spaces between the larger sizes particles.
4. The bed porosity highly affects the pressure drop and inversely proportional to it, this is because that when the porosity increases the resistance to fluid flow through the bed decreases.
5. It is clear that as the porosity decreases the friction factor decreases, in spite of any increase in pressure drop. This is because the friction factor is proportional to power three with porosity, while it is proportional to power one with pressure drop.

6. It was found that the pressure drop through a packed bed is highly sensitive to the packing height and that as the packing height increases the pressure drop increases.
7. Comparing the results of the achieved equations of pressure drop-velocity and friction factor - Reynolds number curves with those of experimental data from literature and Ergun equation results; it indicates that the achieved equations results coincide with experimental results, while the results from Ergun equation was far away from them.
8. The general equation achieved for water and air flow through packed bed can be used for any system of packing, while the singular equation can be used for only one type of packing which is written for it. The comparison between general and singular equations results show quite good agreement between them; therefore, the general equation could be used for all types of packing instead of singular equations.
9. The porosity formulas written for the achieved equations deviate's from experimental results with a very small average percentage error, which means that they are almost identical. The porosity formulas written for the achieved equations have been compared with the results of experimental data and Furnas equation of porosity. The comparisons show a very good agreement between the porosity formula results and the experimental data, while Furnas equation of porosity was far away from the experimental data. So the written porosity formula can be used with confidence with any type of packing system.
10. The semi-empirical equation of minimum fluidization velocity that has been obtained in the present work is comparable with the experimental values of the minimum fluidization velocity for water flow.

6.2 Recommendations for Future Work

The following suggestions could be considered for future work:

1. The achieved equation can be extended to include fluidization conditions.
2. Studying two phase flow through packed bed using the achieved equation.
3. Studying the effect of temperature and heat transfer on pressure drop using achieved equation of fluid flow.
4. Studying the effect of the surface roughness of the material on sphericity and its effects on the pressure drop of fluid flow through packed bed.

الخلاصة

تم صياغة معادلات شبه عملية لجريان الموائع خلال عمود حشوي بالاعتماد على نظرية باكنكهام. تم استخدام نوعان من الموائع (ماء و هواء) بشكل منفصل في كل مرة (جريان طور واحد). تم استخدم انواع واشكال مختلفه من الحشوات وبحجوم مختلفة، وتم دراسة كل واحد منها بشكل منفصل.

تم دراسة العوامل المختلفة التي تؤثر على هبوط الضغط عند جريان الموائع في عمود حشوي كل على حده، هذه العوامل هي سرعة جريان الموائع، مسامية الحشوة، طول الحشوة في العمود الحشوي، قطر العمود الحشوي، معامل كروية الحشوات، قطر الحشوة ودراسة تأثير جدار العمود الحشوي.

تم صياغة معادلة شبه عملية محددة لجريان الموائع لكل نوع محدد من الحشوات المستخدمة وتم تسميتها بالمعادلة المفردة (حشوة كروية الشكل ذات حجم واحد، حشوة غير كروية الشكل ذات حجم واحد ، حشوة كروية الشكل ثنائية الحجم، حشوة كروية الشكل ثلاثية الحجم، حشوة كروية الشكل رباعية الحجم، حشوة كروية الشكل خماسية الحجم و حشوة كروية الشكل متعددة الحجم). تم صياغة احد عشر معادلة احادية من هذه النوعية، ستة منها لجريان الماء وخمسة منها لجريان الهواء خلال العمود الحشوي.

تم صياغة معادلة عامة لجريان الموائع خلال العمود الحشوي تصلح لكافة انواع واشكال الحشوات.

لقد كانت النتائج المستحصلة من المعادلات الجزئية والعامة متقاربة. تم مقارنة النتائج المستحصلة من الحسابات لجريان الموائع خلال عمود حشوي مع عدد كبير من النتائج العملية المستحصلة من المصادر الموثقة، و هذه المقارنة اعطت تطابق جيد جداً، وتم عرض ذلك في جداول و رسومات. تم وضع النتائج المستحصلة باستخدام معادلة ايرجن في هذه الرسومات لنفس الظروف السابقة لغرض المقارنة.

تم كتابة علاقات تجريبية لحساب مسامية المواد لجميع المعادلات المستخدمه في الحسابات، وتم مقارنة النتائج المستحصلة منها مع معادلة فرناس وتجارب عملية مأخوذة من مصادر عملية موثقة وكانت نتائجنا مطابقة بشكل جيد للنتائج العملية.

ان النقطة الدنيا لسرعة الجريان غير المنتظم هي دلالة لبداية عدم الانتظام. وعليه تم كتابة معادلة شبه عملية بالاعتماد على معادلة ليفا لحساب السرعة الدنيا للجريان وذلك لحساب نقطة تغير الجريان الى غير المنتظم.

شكر وتقدير

في البداية اشكر الله عز وجل الذي وفقني لاكمال متطلبات هذا البحث. وانا انهي بحثي لا يسعني واعترافا بالفضل الا ان اتقدم بوافر الشكر والامتنان للاستاذ المشرف الدكتور محمد نصيف لطيف لاقتراحه موضوع الرسالة واشرافه عليها ولمواصلته ومتابعته العلمية للبحث وما ترتب على ذلك من توجيهات قيمه واراء سديدة.

كما اتقدم بجزيل الشكر الى رئيس قسم الهندسة الكيماوية، و جميع اساتذة قسم الهندسة الكيماوية لمساعدتهم القيمة لي طيلة فترة الدراسة ولمدهم يد العون لي خلال اعداد هذه الرسالة. واتقدم بشكري وامتناني الى عمادة جامعة النهريين، لمساعدتهم ودعمهم الدائم لي طيلة فترة الدراسة.

كما اتقدم بالشكر الجزيل الى كافة العاملين في المكتبة المركزية بجامعة النهريين، وذلك لمساعدتهم لي في الحصول على بعض المصادر المستعملة في البحث. وشكري الجزيل الى جميع زملائي و زميلاتي الذين مدو يد العون عند حاجتي اليها في البحث.

ولا انسى ان اتقدم بجزيل الشكر والتقدير الى من ساندني وساعدني على تخطي الصعوبات خلال فترة البحث الى الذين لا مثيل لهم في الدنيا الى أبي وأمي الأعزاء، أخوتي وأخواتي.

م. زينب طالب عبدزيد

دراسة العوامل المؤثرة على هبوط الضغط خلال العمود الحشوي

رسالة

مقدمة إلى كلية الهندسة في جامعة نهرين
وهي جزء من متطلبات نيل درجة ماجستير علوم
في الهندسة الكيماوية
